All this while, Buys Ballot's law that wind is along the isobars with a deviation towards the low pressure and dependent for its strength upon the closeness of the isobars was recognised, and when the phenomena of turbulent motion were explained, it became apparent that the surface-layer was so much affected by turbulence that regularity in the relation of pressure to the surface-wind was not to be expected. But observation showed that in the upper air it might be assumed that the effect of turbulence is negligible, and the geostrophic relation between pressure-gradient and horizontal wind under the influence of the earth's rotation might be regarded as a definite meteorological law, most definite where isobars are straight and parallel. Moreover, it accounts for the development of high pressure, a matter which has been neglected in the study of weather. Wherever the horizontal wind in an air-current is not in agreement with the formula the rotation of the earth will push it sideways, from high to low if the horizontal component is too slow, from low to high if it is too fast. The adjustment will always be operative over the whole mass of the moving air so that the air may be regarded as adjusting the gradient to its motion as a bicyclist adjusts his inclination to the vertical.

In the concentration of attention on the closed isobars of cyclones and anticyclones the study of the straight isobars between them has been overlooked; and it may fairly be asserted that if the origin of the currents with straight isobars can be traced, they may be relied upon to adjust the pressure-gradient to meet the exigencies of the wind in the upper air, which is an indubitable expression of actual energy of vast amount.

Meanwhile, the air is everywhere stratified according to its entropy, and any change in the entropy by gain or loss of heat, by conduction to or from the ground, by radiation to or from the air, or by the condensation or evaporation of water within its mass, will have its effect on the stratification, and the readjustment of the stratification will transform the thermal energy of the air into the actual energy of wind. The currents of straight isobars have, therefore, an obvious claim upon the students of the dynamics of the atmosphere. The extension of the area of the daily map to include the whole hemisphere makes productive investigation possible.

To summarise, our survey leads to the conclusion that meteorology has been mistaken in regarding the cyclonic depression and the anticyclone of a hypothetical sea-level map as the principal agents in control of the energy of weather, and asks for the consideration of the currents in the free air indicated by straight isobars as expressing the real estate of energy in the atmosphere, while the differences in the distribution of entropy and water-vapour associated therewith represent its potential estate.

Recent Developments in Optical Glass Manufacture.*

By W. M. HAMPTON and W. N. WHEAT.

THE demand for particular types of optical glass has changed considerably during the post-War period, largely under the influence of the remarkable development of the modern photographic lens, which has been based on the production of the more extreme types of glass, notably the barium crowns.

This change is shown by the following table of the percentage of the various broad types manufactured by Messrs. Chance Brothers and Co., Ltd., of Birmingham, in the years 1914, 1918, 1929.

	1914.	1918.	1929.
Hard Crown and Zinc Crown	24	29	7
Borosilicate Crown	23	14	18
Light Flint and Baryta Light Flint	27	14	11
Dense Flint	23	27	13
Extra Dense Flint	2	4	16
Barium Crowns	1	12	35

Recent research has enabled the manufacture of the barium glasses to be put on a routine basis, the variation in optical constants from one melt to another not being appreciably greater than is normally obtained with the simpler types. This is largely due to the utilisation of refractories for the melting-pots of a composition which is sufficiently resistant to the solvent action of these very corrosive glasses, thus minimising the trouble, once serious, of dilution by aluminous material dissolved from the pot wall. Improvements in the knowledge of melting technique and of the volatilisation losses which accompany the process of fusion have enabled a more strict control to be exercised over the types of barium glasses which contain a percentage of boric oxide in place of silica, these glasses being indispensable in the manufacture of the modern wide aperture photographic lens. The most extreme example in this series has a refractive index of 1·6140 and a value of V, or reciprocal dispersive power of 59·8, representing the practical limit to which it has so far been found possible to go.

A knowledge of volatilisation losses is of great importance if exact control of the melting of the flint glasses is to be maintained, and it has been established that, within the limits of composition obtained in most optical glasses, the losses of any given oxide may be taken as being directly proportional to the concentration of that oxide, this proportionality holding in the case of lead oxide up to about 50 per cent concentration of PbO. Working at 1400° C. in a covered pot, it has been found that the loss of lead oxide may be expressed as 0·014 lb. per 100 lb. of glass for every one per cent of the oxide present, the corresponding figure for K_2O being 0·12. These values, of course, presuppose constancy in temperature, shape of pot, and length of melting-time.

---

* Substance of a paper read at the Science Museum, South Kensington, on Oct. 29, in connexion with the Exhibition of Modern Technical and Artistic Glasses.

It is easily seen from the above considerations that in the case of an extra dense flint glass, approximately represented by SiO_2, 44 per cent, PbO, 50 per cent, and K_2O, 6 per cent, the loss in pounds of K_2O may exceed the total loss of PbO and the glass after melting actually be richer in PbO than is calculated from the batch composition.

With our present methods of manufacture, perfectly isotropic glasses are probably an impossibility. The degree of homogeneity obtained by stirring is the result of a compromise between various opposing factors. Thus the action of stirring, as the pot and the material of the stirrer itself are very slightly soluble in the glass, will tend to produce veins of different refractive index faster than they can be eliminated by the mixing process if the temperature of the melt is too high, this being due to the rapid increase of the rate of chemical attack with rising temperature. If volatile constituents are present a high temperature of stirring may mean that the surface of the glass, slightly poorer than the rest in the volatile oxide, may be stirred in faster than the resulting veins can be eliminated. On the other hand, too low a temperature produces a heavy 'drag', which may draw in aluminous material from the pot wall in sufficient quantity to render the melting useless.

The most noteworthy recent advance in optical glass manufacture is the production of improved refractories for pots. This work was undertaken recently by Messrs. Chance Brothers and Co., Ltd., with the co-operation of Sir Herbert Jackson, and full-scale pots based on the experimental small-scale samples have been in use for some time. It has been found that the more acidic glasses, such as the ordinary crowns and especially the borosilicates, are best melted in pots having a relatively acidic clay composition—$Al_2O_3,5SiO_2$ being typical. The more basic glasses, such as the flints and the barium crowns, need a lower concentration of silica in the pot material; in these cases a reduction up to 10 per cent of SiO_2 may be made. One of the immediate advantages gained from the use of these new pots was an improvement in the transparency to light of the resulting glasses. The task of measuring the small differences in absorption which exist between various meltings of optical glass is a difficult one, and the figures given in the present paper were obtained by the British Scientific Instrument Research Association, using an apparatus similar to that described by W. D. Haigh.[1]

It has been found that if the absorption per inch of glass material at each wave-length is plotted against percentage of iron oxide present in the glass, the points lie on smooth curves which do not pass through the origin but indicate a definite absorption at zero concentration of iron. However, the absorption in optical glass is largely proportional to the amount of iron oxide present, and the new refractories, coupled with the use of only the purest raw materials, have enabled this to be reduced to a minimum.

The extent of the improvement is shown by the following figures, which are published by permission of Sir Herbert Jackson:

Melt.	Iron per 10^6	Percentage of Light extinguished per Inch of Glass.						
		3650.	4078	4358.	4916.	5460	5790.	6500.
B S.C 5358	180	12 50	3 70	4 62	3·10	2 76	2·88	4 10
B.S.C. 6029	50	2·94	0·82	1 50	1·10	0 76	0 91	1·73

A similar improvement has been made in most of the optical glass types, particularly the dense flints, the barium crowns, and very heavy lead glasses of ^nD up to 1·8; and it is now safely claimed that the optical glasses of the new high transparency type made in Great Britain have a lower absorption of light than any glass of foreign manufacture.

In the efforts to eliminate iron oxide from the glass, work has been done on the purification of sand, and a process has been worked out and patented,[2] using a reducing gas such as sulphur dioxide and chlorine, which has on an experimental scale enabled the iron oxide concentration to be reduced from 0·008 to 0·0025 per cent. The use of purified sands may enable further improvements in transparency to be made in the near future, the present values being considered the maximum possible with existing raw materials.

Although from time to time it has been suggested that the chilling which takes place in moulding may cause heterogeneity in optical glass which is not removed by the subsequent annealing, no direct evidence in support of this has yet been advanced, and it is still considered that the laws approximately represented by Twyman's equation are the only considerations which govern the degree of freedom

Type.	Refractive Index and Value of *V*.	Autoclave Test (4 Atmospheres)	Test using Steam. Steam under Atmospheric Pressure.
B.S.C. .	1·5090 64·3	Unattacked	Unattacked.
H.C. .	1·5159 60·3	Practically unaffected	Unattacked.
L.F. .	1·5475 45·3	Slightly affected	Slightly affected (wipes clean).
Soft Crown	1·5143 56·8	Marked filming	Unaffected.
E.L.F. .	1·5337 49·1	Badly attacked	Surface dulled but wipes clean.
D.B.C. .	1·6140 56·2	Slightly affected	Severe iridescent tarnish.
D.B.C. .	1·6140 59·4	Slightly affected	Completely dulled.

from strain of a block after a certain heat treatment. The essential condition is the accurate measurement of the upper temperature at which strain in the glass block is released in a reasonably short space of time.

Research on methods of testing the resistance of polished glass surfaces to atmospheric attack has led to the abandonment of the old autoclave test of superheated steam at four atmospheres pressure. The abnormality of the conditions of this test must make the results open to doubt, and it has been found that the modified method of testing in water-vapour at atmospheric pressure and a temperature of 80° C. gives results more in accordance with general experience, although the period of the test has to be increased from two hours to two weeks. The revised method of testing puts the various types of optical glass in a different order as regards resistance to surface attack, some of the types previously thought unstable from the results of the autoclave test now being shown to be perfectly reliable, while certain other types previously thought of fair durability are now shown to be very unstable, confirming the experience of the lens manufacturer.

The table on p. 927 shows the classification of representative types of optical glass according to the autoclave and atmospheric durability tests.

Among the new types which have been successfully produced in recent years is a dense barium flint made of ^{n}D 1·6437, $^{n}C - {}^{n}F$ 0·01332, V 48·3, which is as extreme a member of the flint series as the barium crowns are in the crown series. The very heavy lead glasses of ^{n}D up to 1·8 are now produced in large blocks of a degree of homogeneity and freedom from colour never previously attained, this being largely due to the use of the new refractories and correct temperature control in melting.

Obituary.

DR. S. W. STRATTON.

SAMUEL WESLEY STRATTON was born at Litchfield, Illinois, in 1861. He graduated in 1884 from the University of Illinois, where he remained for the next eight years, at first as an instructor, then as professor of mathematics, and finally as professor of physics and electrical engineering. In 1892 he became assistant professor of physics and later professor in the University of Chicago. Nine years afterwards he was invited by the Assistant Secretary of the Treasury to formulate a project for the development of work on weights and measures, and in 1901 was mainly responsible for the Act which established the Bureau of Standards at Washington. Of this he became the first director, retaining the position until 1923, when he was appointed president of the Massachusetts Institute of Technology. He had a lifelong connexion with the American Navy, and in 1898 served during the Spanish American War. This brief summary of his activities shows that the most important part of his work was connected with the Bureau of Standards, which is indebted to him for its existence and for many of its most striking developments.

Stratton was a welcome visitor to the National Physical Laboratory, and spent some time at Bushy House in early years; from this time on the connexion between the two institutions has been a close one. Visitors to the National Physical Laboratory will remember an old chestnut tree near the door of Bushy House, said on good authority to have been planted by Charles II. Round the Bureau of Standards, when founded, was a wood of chestnuts; the site was part of Washington's estate, and tradition says that, after one of his visits to England, Washington took back the chestnuts which formed the nucleus of this wood.

An Electrical Congress, in connexion with an International Exhibition, took place at St. Louis in 1904 and proved to be Stratton's introduction to that international work which for the rest of his life occupied much of his time. This Congress passed two important resolutions: one in favour of a formal International Conference to deal with electrical units, the other inviting the leading technical societies of the world to co-operate in the standardisation of electrical machinery; the first led to the International Conference on Electrical Units in London in 1908, the second to the establishment of the International Electrotechnical Commission.

After the St. Louis Conference, at which I represented the British Government, I spent some time with Stratton at Washington discussing with him, much to my own profit, questions of laboratory organisation suitable for any institute such as those we directed respectively. In 1905 he became a member of the International Committee of Weights and Measures and, as a result, a frequent visitor to this side of the Atlantic

The International Electrical Conference foreshadowed at St. Louis was summoned by the British Government and met in the rooms of the Royal Society in October 1908. Stratton was prominent among the American delegates; he was accompanied by Dr. E. B. Rosa, who had done much valuable work at the Bureau on electrical units.

A distinction had been drawn at the Chicago Electrical Congress, some years previously, between the ohm, the ampere, and the volt, multiples of the C.G.S. units, and the International Ohm, Ampere, and Volt taken to be close approximations to the absolute units, and defined in a manner which it was hoped would permit their realisation with sufficient accuracy for all practical purposes in any fully equipped laboratory. Some of the American delegates would have preferred definitions based only on the C.G.S. units.

The Conference also passed a resolution recommending the various governments interested to establish a permanent International Commission for Electrical Standards and, pending the appointment of this, requested its president, Lord Rayleigh, to nominate a committee to advise as to its constitution and to direct such work as might be necessary in connexion with the maintenance of standards. It was suggested that the functions of the International Conference of Weights and Measures might be enlarged with the view of some combination of effort. The Electrical Conference was of opinion, however, that the Permanent Electrical Commission should be a distinct body.

Stratton was closely concerned in the consequences which followed from these two resolutions and took an active part in the development of each. He was a member of Lord Rayleigh's Committee, and in connexion with the maintenance of standards invited representatives of the Reichsanstalt, the Laboratoire Centrale d'Électricité, and the National Physical Laboratory to meet at the Bureau of Standards in 1910 and complete the work, left incomplete in 1908, of preparing specifications for the standards. The representatives (Dr. E. B. Rosa and Dr. Wolff, Dr. W. Jaeger, Prof. F. Laporte, and Mr. F. E. Smith) met at Washington and worked together during a large part of 1910; their report, "On the Concrete Standards of the International Electrical Units", was issued in January 1912 and has formed up to the present the basis of international co-operation. Dr. Stratton undertook the duties of treasurer of Lord Rayleigh's Committee and collected funds to meet the cost of this joint investigation from certain American societies interested in electrical matters.

The establishment of a Permanent International Electrical Commission was a more difficult matter. The International Conference of Weights and Measures was established to give effect to the resolutions adopted in 1875 by the Metric Convention. The Conference dealt solely with standards of length and mass. To these had been added, as a necessary outcome of accurate measurements of length and mass, the standardisation of a limited range of temperature. A committee of the Conference guided the work of the Bureau International des Poids et Mesures at Sèvres, and Stratton had been a member of this committee since 1905. He believed that the enlargement of the functions of the Conference offered the best solution of the problem of establishing an International Electrical Commission.

After his retirement from South Africa, Sir David Gill became the British representative on the Conference of Weights and Measures, and Stratton found in him a congenial colleague and a cordial supporter, but 1914 prevented the immediate realisation of his ideas. This, however, was achieved, not entirely in the manner originally suggested, in 1927, when the Committee of Weights and Measures adopted the following resolution, ratified later by the Conference: "The International Committee of Weights and Measures approves the organisation of a Consultative Committee for Electricity to advise the International Committee of Weights and Measures on questions relating to systems of Measurement and Electrical Standards". That Committee is now in being and has already done valuable work; the International Committee of Weights and Measures has become the central organisation for the issue of electrical standards. For this purpose it works in close co-operation with the national standardising laboratories, and the standards it proposes to issue will be based on the comparison and co-ordination of the results of these laboratories. At the meeting of the Conference held during the current year, at which Dr. Stratton was present, photometric standards were brought within the ambit of the Committee.

International standardisation did not by any means include the whole of Stratton's work. Since the War, standardisation has been much to the fore in the United States as elsewhere, and Stratton has been a leader on many of the committees dealing with engineering matters. He was a member of the National Screw Thread Commission, and all who have had occasion to study the report of that Commission have appreciated the thoroughness with which its work was done and the value of its results. Stratton was himself a very skilful mechanic. He also served on the National Research Council and on the Advisory Committee for Aeronautics, which under the guidance of Dr. Ames has done much to secure to America a leading place in the scientific study of aviation problems.

Stratton's friends in England welcomed him recently as a delegate to the British Association, Faraday, and Clerk Maxwell centenary meetings in London and Cambridge. These he enjoyed greatly. We met at the National Physical Laboratory and discussed old times, and again at Cambridge, by chance in a bookshop where he was collecting literature relating to Maxwell, as well as during the meetings themselves. He was a guest at Caius College, much impressed by the advantages of college life and the kind hospitality of his hosts.

The end came on Oct. 19, soon after his return to Boston—"No warning, not a moment's illness—just fell forward while talking, that's all" are the words of a letter telling me about it.

R. T. GLAZEBROOK.

MR. ELSDON BEST.

ELSDON BEST, doyen of Polynesian ethnology, died at Wellington, New Zealand, last September. He was born in 1856 at Porirua and had little schooling, but was from his earliest years associated with the Maori population. At eighteen years of age he was in the Poverty Bay district, then emerging from the shadow of Te Kooti's massacres, working in the bush on fencing and felling contracts. He joined the armed constabulary for the, as it turned out, bloodless campaign against Te Whiti, the latter part of his service being in control of a party of 'friendlies' in the bush. In 1883 he went to Honolulu, later moving on to California, engaging in timber work among the redwoods of the Sierra Nevada. He then moved east into Arizona, New Mexico, Texas, and Louisiana, working as a cowboy and as foreman in railroad construction. At the end of 1886 he returned to New Zealand and entered on the period of twenty-five years' intimate connexion with the Maoris which furnished him with the material for his long series of books and bulletins. The latter part of his life was spent in Wellington, on the staff of the Dominion Museum.

Varied experience among men gave Elsdon Best ease of manner, and this, coupled with unusual natural gifts—sound judgment, clarity of thought, and quick decision—left a deep impression on all who met him. He was a master of direct English and had great linguistic abilities, best seen in his mastery of the Maori language, which he spoke in later years more accurately than any living Maori. To this was added the gift of thinking like a Maori. His achievement lay especially in accurately recording difficult data.

In the opinion of the late W. H. R. Rivers, Best was the greatest of all ethnological field workers who have worked in the Pacific. He changed the whole face of Maori ethnology, incorporating in his publications all old data of any value and placing on record a mass of his own data far surpassing, both in quantity and quality, all that had been recorded before him. By his death New Zealand has lost one of the first intellects among her native born.

H. D. Skinner.

Mr. Henry Garnett.

Mr. Henry Garnett, for many years director of Messrs. Flatters and Garnett, Ltd., opticians and scientific instrument makers of Manchester, died on Nov. 3, aged sixty-three years. Henry Garnett was born in Waterford, Ireland, in 1868, where his father was head of Newtown School (of the Society of Friends). There he formed a close friendship with the naturalist J. H. Salter (afterwards professor of botany at Aberystwyth). He was apprenticed to a chemist in Evesham, and during his scant leisure collected a herbarium which was awarded the Bronze Medal of the Pharmaceutical Society. Later he won the Bell Scholarship, and after passing the minor and major (1890) examinations, he secured three silver medals and the Pereira Medal. He worked out, under the direction of Prof. Dunster, the active principles of *Piper ovatum*, and some years later, with Mr. J. Grier, conducted a research into the active principle of ginger, contributing papers to the Pharmaceutical Conference in 1907. Mr. Garnett was keenly interested in birds and plants, and at the time of his death was vice-president of the Manchester Microscopical Society.

We regret to announce the following deaths:—

Major-General Sir David Bruce, K.C.B., F.R.S., president of the British Association at the meeting at Toronto in 1924, who was a pioneer in the study of tropical medicine, on Nov. 27, aged seventy-six years.

Mr. James H. Dellbridge, who was second engineer in Capt. Scott's first Antarctic Expedition, on Nov. 12, aged fifty-nine years.

Prof. W. A. S. Hewins, first director of the London School of Economics, formerly Tooke professor of economic science and statistics at King's College, London, and formerly Under-Secretary of State for the Colonies, on Nov. 16, aged sixty-six years.

Sir Thomas E. Hill, O.B.E., lately medical officer of health for the County of Durham and formerly professor of public health in the University of Durham, on Nov. 25, aged sixty-six years.

Mr. W. F. Reid, an original member of the Society of Chemical Industry and former president of the Society, known for his work on smokeless powder, on Nov. 18, at an advanced age.

News and Views.

The Savilian professorship of astronomy at Oxford, to which Prof. H. H. Plaskett, professor of astrophysics at Harvard University, has recently been appointed, is the oldest chair of astronomy in Great Britain, with the exception of that at Gresham College, London. Like the Savilian professorship of geometry, it was founded in 1619 by Sir Henry Savile (1549–1622), the Elizabethan scholar, provost of Eton, and warden of Merton College, Oxford. John Bainbridge became the first occupant of the chair, Henry Briggs being his colleague in the chair of geometry. Briggs died in 1631 and Bainbridge in 1643, and both were buried in the choir of Merton College Chapel close to the memorial to Sir Henry Savile. During the renovation of the chapel, a good many years ago, the tombstone of Briggs and the memorials to Savile and Bainbridge were removed to the west end of the chapel, where they are to be seen to-day. The immediate successor of Bainbridge was John Greaves, who measured the pyramids; he was deprived of his chair by Parliament in 1648. The chair then passed to Seth Ward, afterwards Bishop of Salisbury, while among his successors have been Wren (1661–1673), David Gregory (1691–1708), Bradley (1721–1762), Thomas Hornsby (1763–1810), Rigaud (1827–1839), W. F. Donkin (1842–1869), Charles Pritchard (1870–1893), and the late Prof. H. H. Turner, who held the chair from 1893 until his death last year.

It is announced in the *Times* that on Nov. 26, at the University of Coimbra, a room was dedicated to the memory of Sir Isaac Newton. At the invitation of the Rector, Dr. João Duarte de Oliveira, the British Ambassador to Portugal presided over the ceremony, and the opening speech was delivered by Sir Frank Dyson, the Astronomer Royal. Afterwards addresses were delivered on Newton's mathematics, physics, and philosophy, and on the law of gravitation; and the Ambassador then unveiled a bronze name-plate in the Sala de Newton in the observatory. Coimbra, once the capital of Portugal, is picturesquely situated on a hill on the bank of the river Mondego. The earliest certain information of a university in Portugal dates from 1288, but it was three years later that a "Studium Generale" was founded at Lisbon. That city not proving suitable, the new school was removed to Coimbra in 1308, but in the next two centuries it was twice transferred to Lisbon and back again, its final removal to Coimbra being in 1537, in the reign of John III. One of its professors in the sixteenth century was the famous Scottish reformer George Buchanan (1506–82), who went to Coimbra in 1547 and was imprisoned by the Inquisition. Mathematics and natural philosophy were first taught there in 1770, after the University was reorganised, and to-day there are five faculties, theology, law, medicine, mathematics, and philosophy. Coimbra has a population of about 20,000, and the students number 1400 or more.

THE Council of the Royal Meteorological Society has awarded the Symons Gold Medal for 1932 to Prof. V. F. K. Bjerknes of the Physical Institute of the University of Oslo, Norway. The medal is awarded for distinguished work in connexion with meteorological science and will be presented at the annual general meeting on Jan. 20. Prof. Bjerknes was born at Oslo on March 14, 1862. He received the degree of doctor of philosophy at Oslo in 1892, and from 1907 onwards has been professor of mechanics and mathematical physics at various universities in Norway and at Leipzig. His work deals almost entirely with the mathematical description of the motion of moving fluids, and especial reference must be made to the two volumes and plates of "Dynamic Meteorology and Hydrography", published at Washington in 1910 and 1911 and in German at Braunschweig in 1912. He has devoted much attention to the theory of cyclones, and has written several of the Norwegian series of Geophysical Publications on this subject. His work played a large part in the development of the Norwegian theory of the 'polar front', and in 1920 he read an important paper before the Royal Meteorological Society on "The Structure of the Atmosphere when Rain is Falling".

As Lord Moynihan remarked in laying the corner-stone of the Wellcome Research Institution on Nov. 25 (see also p. 974), the ceremony might well be regarded as referring to the corner-stone of a long life's work. The various constituent research laboratories of the Wellcome Research Institution are perhaps better known than some of Dr. Henry Wellcome's other scientific activities. Since the time when he paid a visit to the South American cinchona forests in 1879, Dr. Wellcome has given many evidences of his interest in the tropical regions. The results of his archæological excavations in the Anglo-Egyptian Sudan will, when published, throw new light on the racial history of north-east Africa. At the Wellcome Tropical Research Laboratories in Khartoum, Sir Andrew Balfour made war on the malaria-carrying mosquitoes by means of a highly organised system for searching out the mosquito breeding-places and destroying the larvæ. The researches on trypanosomiasis, kala azar, and other tropical diseases were carried out there with most beneficial results. By the establishment of this research centre, Dr. Wellcome has thus contributed materially to the welfare, not only bodily, but also morally, of a large section of the population of the Sudan. In 1914, Dr. Wellcome instituted a special commission to secure improvements in the construction of field ambulances, and equipped and supplied for the Army Medical Service a medical research laboratory which gave valuable service in Palestine and Egypt. In 1905 he founded the Medical Dispensary at Mengo, Uganda; and in 1927 he founded at the same place the Lady Stanley Maternity Centre.

Two hundred years ago, on Dec. 12, 1731, Dr. Erasmus Darwin, the physician and poet, grandfather of Charles Darwin and Sir Francis Galton, was born at Elston Hall, near Newark, being the youngest son of Robert Darwin, "a person of curiosity" who had married a daughter of Erasmus Earle, a sergeant-at-law and a member of Parliament. Entering St. John's College, Cambridge, at the age of nineteen, he graduated B.A. in 1754 and afterwards studied medicine at Edinburgh. He first practised at Nottingham, but after a short time, removed to Lichfield where he married and became a popular physician and a prominent figure in intellectual circles. His ability, his radical opinions, and his advocacy of temperance in drinking gained for him as much fame as his eight-acre botanical garden, his poetry, and his speculations. A friend of Wedgwood, Boulton, Watt, Priestley, Edgeworth, and others, he was a member of the once famous Lunar Society, which arranged to hold its meetings at the time of full moon, so as to facilitate travelling. Few to-day probably read his "Botanic Garden", his "Zoonomia, or the Laws of Organic Life", or his "Phytologia, or Philosophy of Agriculture"; all of which, however, testify to his originality and enthusiasm. An inventor himself of mechanical contrivances, it was with a knowledge of Watt's work on the steam engine that he wrote the oft-quoted lines:

> "Soon shall thy arm, unconquer'd Steam, afar
> Drag the smooth barge, propel the lumbering car
> Or on wide-waving wings expanded bear
> The flying chariot through the fields of air."

ERASMUS DARWIN'S first wife, Mary Howard, died in 1770, and in 1781 he married the widow of Colonel Chandos Pole. Shortly afterwards he removed to Radbourne Hall, and thence to Derby and finally to Breadsall Priory, where he died suddenly on April 18, 1802, at the age of seventy-one years. By his first wife he had three sons, the third of which. Robert Waring Darwin, who married Susannah Wedgwood, was the father of Charles Darwin, who was born in 1809. By his second wife, he had four sons and three daughters, of which Frances Anne Violetta married Samuel Tertius Galton, and had four daughters and three sons, the youngest member of the family, Francis, who was born in 1822, becoming famous as the founder of eugenics. To him was due the erection of a monument in Lichfield Cathedral to his grandfather, Erasmus Darwin.

THE twenty-ninth annual report of the Imperial Cancer Research Fund, presented at a meeting of the general committee on Nov. 25, records another year of the sound work and steady progress which is characteristic of that organisation. The investigations which have been in hand deal mostly, in one way or another, with resistance to cancer. For, helpless as the body may seem in the presence of rampant malignant disease, there is no doubt that it does put up some sort of resistance which, in animals at any rate, may be demonstrably successful. On one hand, Dr. R. J. Ludford has analysed the cellular reactions to implanted cancer, using their reactions to various dyestuffs to identify the cells and to indicate their functional capacity. He has in this way shown that the immunity which can be conferred by the inoculation of embryo skin depends on the connective tissue reaction. Dr. W. Cramer, on the other hand, from the study of mortality statistics, shows that an excess of cancer in one organ is often compensated for in the same community by a deficiency of cancer in other parts of the body: the presence of one tumour, that is, makes the body to some extent resistant to the development of another.

SIR ALFRED EWING's Friday evening discourse on Nov. 27, at the Royal Institution, was a tribute to the life and work of the late Sir Charles Parsons. The genius of Parsons opened up a new era in the production and distribution of power. With Parsons the development of an invention was a patient, laborious advance from experiment to experiment, rejecting the good for the still attainable better. In 1884 Parsons introduced his earliest compound steam turbine; in 1891 he took the further step of continuing the expansion in the turbine down to the low pressure attainable in a condenser. Before long this enabled the turbine to surpass the older engine of Newcomen and Watt in the efficiency with which it converted heat into work. Thanks mainly to further inventions by Parsons, a great modern steam turbine not only develops power in unprecedented quantity, but also with an economy of coal previously unknown. The steam turbine has an almost complete monopoly as a power generator in central stations, except, of course, in countries where hydraulic sources are available. In 1894 Parsons began to apply the turbine to marine propulsion, and in 1897 his little experimental vessel, the *Turbinia*, astonished the Fleet at Spithead. Before long the turbine was adopted in all warships and in many vessels of the mercantile marine. For the largest ships it gives a concentration of effective power that is attainable in no other way.

IN the report of the Newcomen Society for 1930–31, which was read at the annual general meeting held on Nov. 25, at the Chartered Institute of Patent Agents, reference was made to the need of steps being taken for the prevention of the decay of monuments to distinguished engineers and scientific men. The Society itself has done much in this direction and its example might well be followed by other bodies. In one instance a member of the Newcomen Society was able to locate the tombstone of John Blenkinsop, the pioneer of the locomotive, while the Society contributed towards its restoration. In the case of the monument in Row churchyard to Henry Bell, the pioneer of the steam boat, which was falling into neglect, through the Society the Institution of Shipbuilders and Engineers in Scotland was led to inquire into the matter and to arrange for the monument to be cared for. Following its usual custom, the Society, on Aug. 5, 1931, placed a wreath on the memorial at Dartmouth to Thomas Newcomen to mark the anniversary of his death, and early this year took the initiative in arranging for the celebrations of the centenaries of Henry Maudslay and William Symington. The membership of the Society now stands at 321, of which 63 are institutions and libraries at home and abroad which receive the *Transactions*. Up to the present, one of these subscribing institutions has been the Science Museum, and it is with regret that we learn that the call for economy has led to its withdrawal from the Society. In view of the closely related aims of the Science Museum and the Newcomen Society, and the work done by both, it is surely not too much to ask that this decision be reconsidered, especially as the sum at stake is only twenty shillings.

ON Nov. 26, the new Ramsay Memorial Laboratory of Chemical Engineering at University College, London, was opened by His Royal Highness Prince George, in the presence of a large and distinguished assembly representing many branches of science and industry. His Royal Highness, addressing the assembly in the Great Hall of the College, paid a graceful tribute to the life and work of Sir William Ramsay. He went on to say that the new laboratory should do much to bring scientific research in chemistry and engineering into closer contact with the needs of modern industry. The chemical engineer is an earnest student of the mechanism of his processes from all points of view: he deals not only with chemical reactions, but also with questions of suitable materials, heat balances, etc. He also makes full use of every branch of physics and engineering for the production of the perfect manufacturing plant. Such a spirit could well be introduced into all industries; it is not too much to say that a thorough study of these principles would go a long way towards restoring British manufactures. In chemical engineering, as in every other subject, an attempt should be made to maintain a balance, so that pure research, chemical engineering, engineering proper, and economics are linked together and play their part in that scientific harmony which can maintain Great Britain in her position as one of the greatest nations in the world. His Royal Highness then proceeded to open the new laboratory, and afterwards made a full inspection of the building, unveiling the Ramsay Memorial tablet.

IN his address on "Communications" to the Institution of Electrical Engineers on Sept. 22, which has just been published in the Institution's *Journal*, Sir Oliver Lodge points out clearly the essential difference between telegraphic and radio transmission. He says that the theory of wired signalling is not so simple as that of etheric signalling. Historically it came first, but if it had come later it would have been regarded as an improved method, because it enables privacy to be obtained: it is not broadcast, but concentrated. The answer to the question why a wire acts as a speaking tube is not very simple. Most people think that the wire conveys the impulse; but a metal wire is only a piece of matter, and has no power of transmitting ether waves. Directly the waves enter the wire, which they do laterally, they are dissipated, their energy being converted into heat. But the very fact that some of the energy does enter the wire enables the wire to act as a guide or director. The energy does not travel through the wire: it travels in the ether outside the wire. The laws which it follows are such that the main part of the wave does not leave the wire and spread out in all directions, but travels near it and so can be received at the far end without much diminution of intensity. It has to be remembered, however, that the waves in wired signalling are to some extent distorted. They do not all travel at the same rate, and these different rates cause the shape of the complex wave to be altered in the act of transmission. When pulses travel in the free ether they arrive without distortion. Hence it is possible to telephone freely by wireless across the Atlantic, although it is impossible to telephone through a cable.

THE paper read to the Royal Society of Arts on Nov. 17, by M. Hochstadter, W. Vogel, and E. Bowden, on an improved method of constructing high-voltage cables marks an important departure in cable construction which may have far-reaching consequences. It seems that by this new method, high-voltage cables could be installed at a cost which would render them formidable rivals to overhead cables. Large telephone networks, which were formerly strung overhead, are now placed underground, and if the new cable fulfils the expectations of its designers, overhead power lines may gradually be replaced by underground cables. At the present time, manufacturers and engineers have been using oil-filled cables for high-pressure work fairly successfully, but they are expensive and only compete with overhead lines in very special cases. In the new method the cable is drawn inside a pressure-tight steel pipe. Lengths of cable up to 550 yards can be drawn into the pipe without trouble. The pipe is then filled with nitrogen gas at a pressure of fifteen atmospheres, eight cylinders of nitrogen being required per mile. No stop-joints, pressure tanks, or expansion tanks such as are necessary for oil-filled cables are required. The thermal characteristics of the cable being good, it can carry a forty per cent greater load than the normal cable. In the case of a serious fault, the nitrogen employed as the pressure medium would have a quenching effect. Experimental results given in the paper show that the pressure cable shows technical and economic advantages over the oil-filled cable. The authors have benefited by the experience gained during the last twenty years, and their cable seems to have guarded against the ordinary causes of breakdown most scientifically.

A COMMITTEE of the Department of Scientific and Industrial Research, under the chairmanship of Sir William Bragg, has issued a short Report on "The Application of X-ray Crystal Analysis to Industrial Problems". (H.M.S.O.; 9*d*. net.) It is only eighteen years since the discovery was made that X-rays could be employed to determine the internal structure of crystals; and already results of great value to pure science and to industry have been obtained. It was found that the crystalline condition was far more widely extended than had been supposed, and that such substances as cotton, silk, hair, rubber, wood, muscle, and so on were more or less crystalline, and that their behaviour was closely connected with this condition. During the past three years the new method of analysis has been tested at the National Physical Laboratory, and the work, which has been of an exploratory character, is described in the Report. The method can be used to differentiate between mixtures, solid solutions, and pure compounds. In addition, the method yields information as to the size of the crystals in a substance. A material composed of crystals so small that they are well beyond the range of microscopic vision will still yield an excellent diffraction pattern. It is often found that the suitability or otherwise of a substance for a particular purpose depends on the state of subdivision rather than on its chemical composition. Again, it may happen that as a result of treatment the original random distribution of the crystallites is disturbed and the crystals tend to set themselves in some particular direction. This is shown, for example, in a metal subjected to rolling or drawing, and also in such substances as rubber, cellulose, and silk. The Report is illustrated by a number of excellent plates showing typical diffraction patterns for steels, paints, artificial sapphires, and other materials.

ONE of the series of lectures on "Physics in Industry" arranged by the Institute of Physics was delivered on Nov. 26 at the Royal Institution by Mr. A. Whitaker, who took as his subject, "Physics in Sound Recording". The fundamental inventions of the phonograph and gramophone were rendered possible by the general appreciation of many physical principles by the inventors of the last quarter of the nineteenth century, but the application of systematic quantitative investigation was delayed until the beginning of the last decade, when a technique, developed in connexion with telephony and radio, was applied to sound recording. Since this stage, the progress of sound recording and reproduction has been extraordinarily rapid. Knowledge of the limitations of existing systems has also accumulated, and a better appreciation of the extent to which improvement should be attempted. Both the general improvement in quality, which can be confidently anticipated in the light of recent physical research, and the special requirements and applications of sound recording to the gramophone, the sound film, and radio broadcasting, are likely to keep the research laboratories and factories of the industry busy. The sound-recording industries offer a remarkable example of cases where commercial enterprise may be revolutionised almost suddenly by discoveries emanating from their own laboratories or from the research organisations of technically allied industries. These revolutionary changes come, if unexpected, like tornadoes to the ship of commercial enterprise. It is the duty of the physicist in industry to act as weather prophet, and when the tornado arrives, as pilot.

Appliances for counteracting the rolling of a ship on a seaway have often been devised. In the British Navy gyro-stabilisers have been used for several years, and they have been installed on some large yachts. In the *Westinghouse International* for the last quarter of 1931 a description is given of the forty-ton stabilising device soon to be installed on the new 2000-ton Italian destroyer leader *Pigafetta*, now being constructed in the Royal Naval Yard at Spezia. The big gyroscopic machine, the rotating part of which weighs eighteen tons, was designed by the Sperry Gyroscope Company of Brooklyn. It was recently inspected and seen under test by naval attachés of the great powers. The rotor is ninety-one inches in diameter and twenty-two inches in thickness at the rim. The maximum speed of the great wheel is 1350 revolutions a minute, giving a peripheral speed of 32,000 feet a minute. The rotor is said to have been so carefully constructed that only 7·5 ounces of weight change was made on one side so as to ensure an accurate balance and smooth operation. New records in accuracy of gun-fire are expected as a result of the stabilisation. On a calm sea also the ship can be rolled at will by the gyro-stabiliser so as to increase gun elevations and thus secure a longer range of gun-fire. In rough weather the gyro-stabiliser eliminates heavy rolling and increases the ease with which the ship can be manœuvred. It also saves power; a twenty-degree roll is estimated to produce a ten per cent loss of propelling power. It is stated that the *Pigafetta* when completed will be the most efficient warship of its type in the world.

For the past eight years the British School of Archæology in Athens has been engaged in a series of excavations on prehistoric sites in Macedonia, which has established the existence of a uniform metal-using culture distributed throughout central and western Macedonia and Chalcidice during the latter half of the second millennium B.C. The affinities of this culture lie unmistakably with Troy and north-west Asia Minor; but it has at the same time such striking affinities with the early Helladic culture of south and central Greece itself, which is held to be of south and west Anatolian origin, that a common source for both cultures may be inferred. In a survey of the results of the School's work in this field, which Mr. W. A. Heurtley, the Director, contributes to *Man* for October, it is pointed out that while the persistence of the old Anatolian element, despite interruptions, into the iron age and the period of Greek penetration, has been established in central Macedonia and Chalcidice, in western Macedonia there is a gap in the records. Of the three sites excavated there, two, Servia and Amenochori, were occupied after the end of the early bronze age, while the third, Boubousti, is late bronze and early iron age. The north-west corner, around the head-waters of the Crna river, still remains unexplored. Investigation of this area is imperative to complete the School's programme in Macedonia. Two campaigns will be required, for which the goodwill of the Jugo-Slav authorities is assured. Further, Mr. Heurtley points out, such exploration may furnish evidence which will date the first period of Vinča, a result of which the significance was indicated by Prof. Vassitz's communication to the recent meeting of the British Association, in which he dealt with his excavations on that site.

The famous Roman camp at Housesteads, on the line of the Tyne-Solway Wall, is now the property of the National Trust, so that its vivid story of activity and conquest will be told to the people for all time. The camp is but an incident in a great defensive scheme, and the aspect which arouses the grand impression of the skill and indomitable force of the Romans is the wide view of the Wall itself running for miles up hill and down dale, deviating from the straight path only when some surface feature of the country offers special advantages for defence. Dr. Vaughan Cornish makes the admirable suggestion that this larger aspect of the Roman handiwork should be enshrined in a Housesteads National Park. The area would be about nine miles long by five broad, with Housesteads as its middle point, and would include the course of the Wall from near Carraw on the east to the summit of the ridge between Caw Gap and Haltwhistle Burn on the west. It is an unspoiled country, suitable in its remoteness and non-arable nature, grand in its possession of basaltic cliffs or 'crags', rising to 1230 feet, of which the Wall makes full use, and which afford glimpses of the Cheviot borders and the mountains of Lakeland. It is a park which could be devoted to recreation, education, and research. Dr. Cornish's views are contained in a pamphlet based upon his British Association address and published at the Map House, 67 St. James's St., S.W.1, at the price of one shilling.

Whether or no evolution has come to a close in wild Nature, animals under the control of man appear to be continuing to vary as much as ever. At the British Aquarists' Association show held in October, a blue goldfish of a scaleless variety was exhibited, and the present writer has seen an ordinary scaled goldfish of a steel-blue colour. Of late years, golden-yellow goldfish, as opposed to the red, which is usually the actual colour of 'gold' fish, have become quite common; it is tempting to regard these as representing the original variation, which may have been supplanted in public favour by the more richly coloured red variety, when this appeared; but Darwin, in "The Variation of Animals and Plants under Domestication", quotes an ancient Chinese work on the production of fish with vermilion scales. One fact about the colour variations of goldfish is worth noting: though gold-and-black, gold-and-white, and tricolour specimens are familiar, like the self-coloured gold and silver, black-and-white is almost as rare as blue, which seems curious. In canaries, Mr. G. E. Weston recently recorded in *Cage-Birds* the exhibition of a nearly black variety; whites and greys, like the yellow goldfish, have been in evidence for some years, but these are undoubtedly not new, having been mentioned by old authorities.

A note by Mr. C. S. Webb in the *Avicultural Magazine* for November throws light on what has always been a puzzle in the habits of trogons—why the neotropical species of this ancient tropicopolitan group, which, unlike the Old World forms, are mainly frugivorous, should fly at their food and pluck it on the wing instead of settling to gather it. He saw, in Guiana, a trogon alight on a bush about twelve feet away from some berry-bearing branches and, after a pause, fly out at these seven or eight times, each time plucking a berry and returning to its first perch to eat it. The reason for such an apparent waste of energy was revealed as soon as the trogon left, for the next fruit-eating bird to arrive, a tanager, settled among the berries and instantly fell a victim to a tree-snake which had been lying in ambush. It is quite possible that the fruit-eating habit in American trogons is a comparatively new one in the history of the race, and that the habit of darting out even at this stationary food is merely the blind instinctive continuance of the original fly-catching habit; but the above observation shows that it is certainly justified by results, and may perhaps, after all, be attributed to intelligence. To sit on a perch and dart out at any food looks lazy in a bird, but the habit at any rate encourages observation and gives time for reflection.

In the interests of the progress of forestry in Great Britain, it is pleasing to note that *Forestry*, the journal of the Society of Foresters of Great Britain (founded a few years ago), maintains its level of excellence. Vol. 5, No. 1 (June 1931), commences with the address delivered to the Society at the annual meeting of this year by the president, Dr. J. D. Sutherland. Two departures have been inaugurated in this number. The president had suggested that a series of biographical memoirs on notable men who have contributed to British forestry should be commenced. In the present number Dr. Sutherland contributes an article on Archibald Menzies, the botanical explorer, whose name is well known to the British forester in connexion with the Sitka spruce. The second departure is due to a suggestion of Sir R. L. Robinson that all available knowledge on the subject of the Sitka spruce should be published in a series of articles, and Mr. A. D. Hopkinson begins with a paper entitled "Sitka Spruce and other Conifers on the Queen Charlotte's Islands". Succeeding articles will deal with the species in Great Britain, its establishment, growth and production, and timber. Mr. Frank Scott contributes an article on "The Place of Douglas Fir in Scottish Forestry". The remarkably rapid growth of this fir in youth led to its being planted in many unsuitable localities; damage and destruction from wind, snow, frost, and, later, disease, almost inevitably followed—and the tree went out of favour. Mr. Scott sets himself the task of inquiring, point by point, into the true position and possible future of the Douglas fir in Great Britain, confining his remarks to Scotland, although they will be found to be equally relevant to many parts of England and Wales.

Among the recent acquisitions of the Department of Geology of the British Museum (Natural History) is a mammoth tusk from Siberia, nearly fourteen feet long, and probably the largest known, presented by the Rowland Ward Trustees. The Anglo-Persian Oil Company has presented some Cretaceous Mollusca from Persia, including some gigantic Rudists, one of which is eighteen inches high and nine inches across. These bi-valves, like the oyster, become fixed by one valve when young; but in the Rudists the lower valve further becomes extremely thickened and has a lattice-like internal structure, and grows upwards to form a pillar-like mass, which is often curved. The soft parts remain small, lying in the shallow cavity at the top of the pillar-like lower valve, and are covered by the lid-like upper valve. The Department of Botany of the Museum has received a valuable collection of West Indian marine algæ through the work of Mr. G. Tandy, Assistant Keeper in the Department. There are about a thousand mounted specimens, representing about 425 species. The algæ were collected mainly by Mr. Tandy while working at the Marine Biological Laboratory of the Carnegie Institution of Washington at the Dry Tortugas, Florida; others were collected by Mr. John Colman, who was working on zoological problems. This close co-operation in the study of a small area resulted in the discovery of a number of organisms which had not been found by the specialists who had previously worked over the area. The Friends of the National Libraries, with the co-operation of one of their members, Mr. Basil H. Soulsby, have presented to the general library of the Museum four rare Linneana, including a sixth edition (1764) of Linnæus's "Genera Plantarum", with the rare portrait of the author at the age of thirty-three years, engraved by Tanje, only found in a few copies of this edition.

That the law protecting the dwindling mammals of Australia lags behind enlightened public opinion is the conviction of the Council of the Royal Zoological Society of New South Wales. The Report presented to the annual meeting at Sydney states that the removal of protection from the opossum during an 'open' season was opposed by the Society and others, but was granted by the State partly on the ground of the strenuous economic period. It was claimed officially that extreme care would be exercised in the issue of permits to kill opossums (showing that the State recognises the difficulties), and strict rules as to the methods to be employed were issued, and yet, according to the Council's Report, the resulting slaughter was carried out in the usual uneconomic manner (*Australian Zoologist*, August 1931, p. 2). Probably 50 per cent of the skins taken represented females carrying young, which were uselessly destroyed. "So long as our so-called protection laws are subject to suspension at a few days' notice by a Minister acting under political pressure, so long will the continued existence of our native fauna be threatened."

Although much has been done of late, as, for example, by the establishment of the Joint Standing Committee on Library Co-operation, and by the pooling of library resources through the National Central Library, to enable readers in Great Britain to obtain books of which they know the existence, at the present time, at least on the technical side, the majority of people are not aware of a large proportion of the published data available throughout the world. Librarians have long realised that their duty is not merely to store books, or even to produce them on demand, but to put the serious reader into contact with the books on his subject, whether they are in the library or not. In the past they have been unable to fulfil this duty for lack of a comprehensive subject-catalogue of the best books on every subject published in different countries. To meet this need, the forthcoming publication is announced of an "International Bibliographical Guide" in five volumes (The Weardale Press, Ltd., 26 Gordon Street, London, W.C.1. Price £2 in advance, and £4 12*s.* a volume as issued). Its lists of books are being compiled and annotated by experts in every subject, who treat only of the works published in their own country. Although, probably, no librarian would contemplate the purchase of every book described in the Guide, it should be an indispensable tool whereby to ascertain what publications exist, and through available facilities to connect the reader with the literature of his subject. The Guide will also be of benefit to the book trade by indicating books on any subject.

PART I., "Medical Tables", of the Registrar-General's Statistical Review for 1930 has been issued (H.M. Stationery Office. 7*s.* 6*d.* net). The birth-rate per 1000 persons living was 16·3 (the same as that for the preceding year), the death-rate per 1000 total population was 11·4, and the deaths of infants under one year per 1000 live births was 60; all of these rates are the lowest recorded. The death-rate from all forms of tuberculosis was also the lowest recorded, 898 per million living. Puerperal deaths, however, show no improvement, being 4·40 per 1000 live births, compared with 4·33 in the previous year. The crude rate for cancer was 1454 per million living, against 1437 for 1929. Some comfort may be derived from the statement that the comparative mortality from cancer has been almost stationary during the last few years, if allowance is made for differences in the age constitution of the population. The toll of the roads is increasing, deaths resulting from accidental injury by mechanical vehicles being returned at 6404, as against 4492 in 1927, 5251 in 1928, and 5799 in 1929.

THE Marine Biological Association, Plymouth, has issued a second edition of the account of the marine fauna of the Plymouth district. A brief description is given of the principal collecting grounds and their physical conditions, with a note of the more common and characteristic species found in them. Then follows in systematic order the list of species (pp. 25-331) for which the exact locality is known. The initials of one or more observers are appended to the records, and under many of the species particulars are added as to relative abundance, breeding period, and occurrence of larval stages in the plankton. A list of works referred to and an index to genera and synonyms complete this useful volume, which is published at the remarkably low price of 2*s.* 6*d.* Congratulations are due to Dr. E. J. Allen, Dr. M. V. Lebour, and Mrs. Sexton, who have been chiefly responsible for the preparation of the volume.

IN the progress of the City of Leicester Museum and Art Gallery the past year has been remarkable for the extension of the Museum and Art Gallery building. This enlargement, consisting of a three-story block, contains, besides exhibition rooms, a muniment room and a research room, for the safe keeping and study of local records. But almost as great a gain has been the improvement in lighting and general attractiveness, for the dullness of museums has had much to do with their unpopularity; and the introduction of a fish-pool and fountain in the mosaic floor of the well-light of the central court was discovered by visitors to be a refreshing innovation.

ATTENTION may again be directed to the issue of *Building Science Abstracts* by the Department of Scientific and Industrial Research, published monthly by H.M. Stationery Office. Each number costs 9*d.* net, the annual subscription being 10*s.* This periodical contains a number of classified abstracts of papers in British and foreign journals, etc., dealing with all aspects of building, including timber, paints and varnishes, glass, metal, and design of structures, and it will be of great service to architects and others interested in building.

IT is announced in *Science* that honorary doctorates have been conferred by the University of Paris on Prof. Walter B. Cannon, professor of physiology in Harvard University, and Prof. Henry Fairfield Osborn, president of the American Museum of Natural History.

MESSRS. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, have just published another (New Series, No. 26) of their useful classified lists of scientific periodicals and publications of learned societies. It should be of great service to librarians and others desirous of completing sets upon their shelves.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A radium officer at the North of England Radium Institute, Newcastle-upon-Tyne—The House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne (Dec. 7). An assistant lecturer in engineering at the Cardiff Technical College—The Director of Education, City Hall, Cardiff (Dec. 12). A lecturer in mathematics in the department of physics and mathematics of the Birmingham Central Technical College—The Principal, Central Technical College, Birmingham (Dec. 19). A Kirk Duncanson Fellow of the Royal College of Physicians of Edinburgh—The Secretary, Royal College of Physicians of Edinburgh, 9 Queen Street, Edinburgh (Jan. 15). A bacteriologist at the Wellcome Tropical Research Laboratories, Khartoum—The Director, Wellcome Tropical Research Laboratories, Khartoum, Sudan.

Supplement to NATURE

No. 3240 DECEMBER 5, 1931

Reviews.

A New Summary of Knowledge.

An Outline of Modern Knowledge. Edited by Dr. William Rose. Pp. xv + 1103. (London: Victor Gollancz, Ltd., 1931.) 8*s.* 6*d.* net.

THE publishers of this new composite book by twenty-two able and well-informed writers are fully justified for part of the large claim they make for it as the "cheapest book of our generation" and the "most remarkable event in publishing history". It contains, in just over a thousand pages, twenty-four essays on different branches of knowledge by acknowledged experts, and it offers the whole in a volume little larger than a new novel and at only a shilling more. Its production is welcome evidence, like so many similar popular series, that there is an increasing appetite abroad for something more than mere amusement or sensation, and we believe that the statistics of public libraries are beginning to tell the same tale. It is evident also that no reviewer, however conscientious, could hope to give an adequate account, much less a judgment, on so varied a menu served up by chefs each of them far more accomplished in his own branch than himself. The most that can be done is to give a general idea, noting outstanding excellences, and then to qualify—as is also necessary—the impression that might be created by the publishers' notice.

In a general way, then, it must be noted that the book is rather a summary of views than of news. The nearest analogy would be the collection in one volume of the general articles in an encyclopædia, though even from this point of view there are many lacunæ. There is practically nothing on aeronautics, education, engineering, law, linguistics, medicine, war, wireless, to name a few of the great modern topics for which one turns to an encyclopædia. In most of the articles the writer's chief attention is given rather to what has been thought about his subject and its general tendency than to the actual achievements of the workers. Thus, we have a chapter on the canons of literary criticism, but nothing on the modern works of literature themselves; an admirable review of the evolution of music since the Middle Ages, but only two casual references to Elgar and Sibelius for contemporary music; a chapter, as well expressed and stimulating as we might expect, from Sir Arthur Thomson on biology and human progress, from which it would be very difficult to find out the exact position of any particular question now in debate.

There are, of course, several articles of a more definite and informational kind, and the unevenness in this respect seems to indicate some weakness in the editing. A quite admirable introduction to mathematics by Prof. James Rice—the best bit of popular exposition in the book—should have had a more leading place. Profs. Seligman and E. A. Gardner both contribute accurate and well-filled summaries of their own subjects, one on the distribution of the different types of the human race, and the other on 'archæology', meaning in the latter case practically the artistic remains of early Greece. Prof. T. E. Gregory gives a sound and well-balanced statement of modern finance, but it is not exactly popular. Like most of the essays, it requires to be read as a whole and with a good deal of concentration. One writer who succeeds best—and this is very well—in covering his subject as a whole, giving both its main principles and their historical development and changes in recent times, with interesting illustrations, is Prof. C. H. Reilly, of Liverpool, whose forty pages on architecture are masterly.

There is much other first-rate material in the book, and it need scarcely be said that the whole is well worth the money; but as a book of reference—the other claim made for it—it cannot be recommended. It is a series of monographs bound up together, and these monographs leave untouched some of the most important domains of modern knowledge. One singular example of this—perhaps the most striking example of want of proportion and planning as a whole—is the almost complete absence of definite historical knowledge and the profusion of the discussion of sex. It must be added, in fairness, that one of the articles dealing with sex, that by Prof. F. A. E. Crew, director of the

Department of Research in Animal Breeding in the University of Edinburgh, is, side by side with Prof. Reilly's, that in which contemporary work is described with most accuracy. It is, of course, a little specialist treatise in itself, differing in that respect *toto cœlo* from Prof. Rice's introduction to mathematics.

Prof. Hearnshaw gives a closely packed article, with his accustomed precision and good arrangement, on historiography and how historians have regarded their work, and whether history could be considered as a science. But, when we ask what happened to anybody or any one thing in particular, we may search the book in vain. Mr. Cole discourses of Marx and capitalism, and shows that the Soviet system is a logical outcome of Marxism; but for how the Russian system came into being, we have to look elsewhere than in this book. Perhaps it will be felt that this is to ask too much of a thousand pages, but is it not a very important part of 'modern knowledge', and is there any reason why one should take down one 'book of reference' for the theories men have had about society and have—without warning—to find others to tell us how they have acted in practice? One reader at least would have gladly spared some of the more revolting absurdities of psycho-analysis for a few solid facts of history. England in the index has just fifteen items to its credit, Russia nineteen, while sex spreads out to seventy-four, being, except psychology and psycho-analysis, far the largest heading.

F. S. Marvin.

Topography and Tradition.

Joshua: Judges. By John Garstang. (The Foundations of Bible History.) Pp. xxiv + 423 + 73 plates. (London: Constable and Co., Ltd., 1931.) 20*s.* net.

In the topographical exploration of Palestine, our countrymen have always taken a leading part. The names of Sir Charles Wilson, Sir Charles Warren, Sir Charles Watson, Col. Conder, and Canon Tristram are eminent, and the great survey of western Palestine undertaken for the Palestine Exploration Fund by Conder and Captain H. H. Kitchener (afterwards Lord Kitchener of Khartoum) is fundamental. Under the present regime, the Mandatory Power is responsible for the protection and maintenance of antiquities, and the British School of Archæology in Jerusalem has been training a new generation of excavators and explorers.

In the first years after the War, Prof. Garstang was both Inspector-General of Antiquities and Director of the British School, and rightly devoted much of his time to co-ordinate in the archives of the Department what was already known about rites and monuments, and to supplement this by the work of the School and its students. Seven years of this experience "impressed him deeply", as it must anyone in his position, "with a sense of material reality underlying the historical narrative" of the Israelite conquest of Palestine; and in comparative leisure thereafter he has put together this valuable collation of traditional history with topographical fact.

In the received text of the books of "Joshua" and "Judges" there are discrepancies and contradictions; but literary criticism has, at all events, separated archetype from gloss and commentary, and earlier from later points of view among Hebrew editors and interpreters. By the single expedient of concentrating topographical inquiries on the earliest passages, which are relatively free from discrepancies, not only has the circumstantial veracity of the narrative been established, but a solution has also been discovered for the grave chronological difficulties which have been found in it by some scholars. So long as it was thought necessary to divide the exploits of the 'Judges' of Israel into regional and concurrent sections, the earlier events were inevitably 'brought down' to periods which preceded the establishment of the united kingdom of David and Solomon by only about one-third of the recorded intervals. It was as though a 'higher criticism' of English history had synchronised, on geographical grounds, the doings of the Houses of York and Lancaster, or the Norman and Angevin kings. The consequent difficulties, however, disappear, and Israelite history fits with Palestinian, when the 'longer chronology' is restored, and the 'exodus' and subsequent invasion of Palestine are assigned to the latter part of the fifteenth century B.C., when the recent Egyptian conquest of Palestine had broken up local dynasties and tribal groupings, but had itself in turn failed to maintain control of the political situation. The conquest, as was perhaps inevitable—for it was a war of revenge after the Hyksos oppression of Egypt—had been a reign of terror. "I sent the hornet before you, which drave them out" (Josh. xxiv. 12), and the "hornet" is the well-known symbol of the kingship of Lower Egypt. This 'historical background' and its implications are the subject of Prof. Garstang's first sections (§§ 1-2), in which the stage is set for the Israelite invasion by a general survey of the political and military topography of Palestine.

The military operations themselves (§§ 3-8) are in all respects the most effective part of the story. The sites are known; there has been excavation at Jericho, under Prof. Garstang's own direction; the waters of Jordan obligingly "rose up in one heap a great way off" in 1927, as in 1906, 1267, and in Joshua's day, the cause being the collapse of its steep alluvial bank, so that in 1927 "no water flowed down the river bed for twenty-one and a half hours". That the Israelites' good fortune likewise was due to earthquake seems, as Prof. Garstang notes, to have been in the earliest version of the story; in the Song of Deborah: "when thou marchedst out of the fields of Edom, the earth trembled".

Less spectacular, but no less important, contributions to the subject are the remaining topics, the "Settlement of the Tribes" (§§ 9-13) and "The Tribes under the Judges" (§§ 14-20), and the very full appendix in which the places, great and small, mentioned in the narrative are described and so far as possible identified with actual sites.

The value of the work is greatly increased by a large number of photographs, which give a very clear notion of the present state of the countryside, and of the vast amount of evidence awaiting exploration in its many mounds and other inhabited sites.

J. L. Myres.

History of Medicine.

Sixty Centuries of Health and Physick: the Progress of Ideas from Primitive Magic to Modern Medicine. By S. G. Blaxland Stubbs and E. W. Bligh. Pp. xvi + 253 + 55 plates. (London: Sampson Low, Marston and Co., Ltd., n.d.) 15*s.* net.

The object of this volume, as is set forth by Sir Humphry Rolleston in the introduction and the authors in the preface, is not to be a complete history of medicine, but rather "to seize the prevalent ideas of each age of medicine with some notes on the public health, to present them with due regard to the colour of the age, and ruthlessly to ignore minor names".

The work consists of twenty chapters, the first ten of which, covering the period up to the end of the sixteenth century, and the nineteenth, on the growth of hospitals and the sanitary idea, are the work of Mr. Stubbs, while the remainder are due to Mr. Bligh.

In the first chapter it is shown that prehistoric man is to be credited with a higher level of health than the products of most civilisations, inasmuch as he escaped most if not all of the diseases due to modern diet, although his ideas of medicine or health were but a crude mixture of the animal and the animistic. The Sumerians, Babylonians, and Assyrians, who are next considered, lived a reasonably hygienic life, though their knowledge of medicine and disease was closely intermingled with superstition and magic, as is illustrated by several quotations from Campbell Thompson's "Assyrian Medical Texts". Foolish and disgusting as many of the modes of treatment then were, they were no worse than those ordered 1600 years later, the object in both cases being to disgust the demon who was regarded as the cause of the disease.

Special emphasis is laid on two important contributions of the Semitic peoples to public hygiene, namely, the institution of the seventh day of rest and the prophylactic code of ritual hygiene and cult cleanliness as set forth in Leviticus.

In ancient Egypt, where, as Armand Ruffer and others have shown, atheroma, arthritis, and every form of dental disease were prevalent, advance was restricted by magic and the confinement of hygienic measures to the king, priest, and nobles, with little regard for the mass of the people.

Before dealing with the remarkable contributions made by the Greeks to the progress of medicine, Mr. Stubbs controverts the widespread opinion that prior to their advent there was no science in medicine but only meaningless magic and silly superstition. The beginnings of western science are to be found in the Minoan, Trojan, and Mycenæan civilisations, especially the first, as illustrated in Crete by the discoveries of Sir Arthur Evans, who found in the palace of Knossos a system of sanitation superior to that of any ancient or medieval civilisation.

A special chapter is devoted to Hippocrates, with numerous quotations from his works to show their modern spirit. The inheritors of Hippocrates and the state of medicine at Alexandria and Rome down to A.D. 200 are next considered, special attention being given to the work of Galen. Although Rome had no science, it is to be credited with an excellent system of hygiene, as exemplified by the construction of aqueducts and sewers and the foundation of hospitals.

The decline in medical science which took place during the Middle Ages, though not primarily due to medieval religion, was undoubtedly hastened thereby, and it was only by the intervention of heretics such as the Nestorians, Roger Bacon and Albertus Magnus, the Islamic invasion of Europe, and the newly discovered learning of ancient

Greece and Rome that the destruction was not rendered complete.

The remaining chapters deal with the foundation of the modern period of medicine in the fifteenth and sixteenth centuries; its progress in the seventeenth century, as illustrated by the birth of modern physiology, the foundation of the Royal Society and the work of Sanctorius and Harvey, the introduction of chemistry and mathematics into medicine by Paracelsus, van Helmont, and Borelli, the microscope and the discovery of germs, the clinical supremacy of Sydenham; the progress of medicine in the eighteenth century, which is described as an era of hygiene in which a lull took place in microscopic research; and the epoch of modern medicine.

The text is liberally interspersed with reproductions of contemporary illustrations, and a short bibliography of readily accessible English works supplementary to those mentioned in the text is appended. The volume may be warmly recommended to those in need of a well-written and lively introduction to the study of medical history.

History of Demography.

Theories of Population from Raleigh to Arthur Young: Lectures delivered in the Galtonian Laboratory, University of London, under the Newmarch Foundation, February 11 to March 18, 1929, with two additional Lectures and with References to Authorities. By Dr. J. Bonar. Pp. 253. (London: George Allen and Unwin, Ltd., 1931.) 10*s*. 6*d*. net.

DEMOGRAPHY, or the study of births, marriages, and deaths, is the science at the base of politics and economics, and its prime necessity is an accurate census, repeated at regular intervals. The author traces its rise by a series of examples from the seventeenth and eighteenth centuries, and it adds to our pleasure that he selects these from our own countrymen, for we know the economic conditions they were experiencing, and the constant question between the growth of population in city and country conditions. Raleigh, Hobbes, Bacon, and More were all great, and the incarceration in the Tower of the former gave us the "History of the World". Therein is praise of the dissimilitude of Nature, and the very practical consideration of an Ark, 600 ft. by 100 ft. by 60 ft. deep, leads Raleigh to conclude that Noah probably selected his animals, so that they by breeding gave us all the present species.

Harrington was a visionary, but Graunt, one of the original fellows of the Royal Society, elected in 1663 for his book on "Natural and Political Observations on the Bills of Mortality", was of a different order. It is based on his collected figures, and these were extended also to the country, so that the population of England is estimated at about 6½ millions, with about a fourteenth of the whole in London. He and all are shy in asking for a census, as it was deemed to be against the law of God.

Petty was a greater man, and his consideration of social conditions is almost such as we might hear to-day; his great remedy is migration, Nature's own method for excess of population. Halley, the astronomer, used Graunt's tables to consider life insurance, adding the tables of mortality of Breslau. Derham quotes the providence of God in reducing the longevity of man at first to 120 years and then to 70 years, so that "the peopled world is kept at a convenient stay". Süssmilch used all tables and applied them to the world, calculating percentages of all ages, and he even considered epidemics. Hume was more economist than demographer—and indeed the whole was then mainly an economic question. Price supported a sinking fund, and his remedy for the National Debt was an increase in the population, but Howlet contested most of his basal work.

Arthur Young, lastly, discusses population and agriculture. His life-work was to improve agricultural methods, and he never seems to have quite understood that manufacture and agriculture go hand-in-hand. He corresponded with Malthus, who later had the benefit of the first accurate census.

The subject is an interesting study, especially when as here illuminated by the mind of an author widely read in world history and the problems of economics. We imagine his view to be that population and world conditions present similar curves, the former lagging a little behind the latter, but that the number of censuses behind us is too few to allow the drawing of such at present.

Animal Aggregations.

Animal Aggregations: a Study in General Sociology. By W. C. Allee. Pp. ix + 431. (Chicago: University of Chicago Press; London: Cambridge University Press, 1931.) 22*s*. 6*d*. net.

DEEGENER'S great work "Die Formen der Vergesellschaftung im Tierreiche", 1918, was completely spoilt for us by its cumbrous classification of animal aggregations and the impossibility of assigning many cases to any single group. He saw that many animals normally live in communities consisting of a single or a few species, and was inclined to regard this as a general phenomenon. Earlier, Espinas, in 1878, had developed similar views. "Communal life, therefore, is not an accidental fact in the animal kingdom; it does not arise here and there fortuitously, and, as it were, capriciously . . . but . . . a normal, constant, universal fact." Wheeler, in 1930, classified aggregations into loosely integrated associations and more permanent societies. The extreme cases of the latter are in ants, termites and bees, and in man. These are not comparable, but Wheeler has shown more than thirty cases of prolonged association of young and adults in five orders of insects. In most cases it is an association of mother and offspring, the chief bond being 'trophallaxis' or mutual feeding. This family basis accounts for much of the phenomena of flocks, herds, and human societies, a certain amount of recruiting from outside being allowed.

Family association is easily understood, but Allee reviews much more widespread aggregations in Nature. He gives many examples of such from unicellular organisms, in which chemical and physical conditions often play a markedly forcing part, to higher and more active organisms, the movements of which, before they come together, may be termed 'random'. Sexual phenomena, moisture and drought, sleep, hibernation, etc., are all factors conditioning aggregations, and the individuals in the same keep together by touch, smell, vision, sound, and perhaps more subtle methods. Generally an aggregation consists of a single species, but allied species are frequently found together, and even the association of animals of different phyla is not unusual. The most common cause for most animals is the 'physiological state' of the gut, the need for food, but this certainly fails to explain the immense numbers often found together in the sea.

Space forbids us to attempt to follow our author into the large number of examples he gives of the harmful and beneficial effects of aggregations. He refers, not ultra-critically, to a host of research papers, and, giving the facts and references accurately, he merits the deep gratitude of busy teachers. In particular we are interested in the variety of the phenomena giving protection from toxic reagents and in the mass physiology of spermatozoa. The problems due to crowding cannot be absent from any chapter. As growth and reproduction may be either stimulated or inhibited in different animals by crowding, there is full scope for research here and the cases cited suggest many practical problems. Four cases affecting the sex ratio are cited as having survival value. Crowding produces morphological effects in many insects, such as the locusts, the story of which is so fashionable to-day. Some insects, too, show the highest known states of social organisation. It is clear that we know little or nothing of the less closely knit insect aggregations, and here there is a vast field for research as to how far in such there may be a co-operative effort, which is victorious in the struggle for existence.

The principle of co-operation in animal aggregations has in Prof. Allee an enthusiastic advocate. "Evidently mutual interdependence, or automatic co-operation, is sufficiently widespread among the animal kingdom to warrant the conclusion given above that it ranks as one of the fundamental qualities of animal protoplasm, and probably of protoplasm in general." Later it is claimed that co-operation and the struggle for existence are the two great principles in determining the trend of animal evolution. About 125 examples of aggregations are given, and more than a hundred of these are not connected with breeding. A phylogenetic tree of animals shows the groups to which these animals, supposed to be co-operating automatically, belong. Some might question this co-operation in unicellular organisms, and we must surely eliminate all colonial animals with repetitions of parts physiologically connected. Coming to the higher forms, it is significant that such surviving animals as are supposed to retain characteristics primitive in their evolution show the minimum of such automatic co-operation. We should ourselves regard it as a quality which has arisen many times over in the evolution of animals, and not a fundamental quality of animal protoplasm.

We have enjoyed reading this book and we thank the author for many suggestions, both for laboratory workers and for field naturalists. Both classes should have this book on their shelves for reference. The study of animal aggregation is clearly of great importance, not merely theoretically but also practically applied to man himself, the phenomena in whose social organisation may find useful analogies in such studies on animals.

Problems in Parthenogenesis.

La parthénogenèse. Par Prof. A. Vandel. (Encyclopédie scientifique : Bibliothèque de biologie générale.) Pp. xix + 412. (Paris : Gaston Doin et Cie, 1931.) 32 francs.

THE subject of virgin birth in animals is so interesting that it is curious that, until now, only two books have been devoted specially to it, those of Delage and Goldsmith (1913), and Winkler

(1920). The last decade has seen so much important progress, however, that a new work is a desideratum, and for its preparation no author is better fitted than Prof. Vandel of the University of Toulouse, as is abundantly proved by his researches on the isopod *Trichoniscus provisorius*, his development from them of the theory of geographical parthenogenesis, and his summaries of modern aspects of the general problem. His book is authoritative and is definitely a landmark.

The appeal is primarily to a scientific audience possessing a certain acquaintance with recent developments in biology. Accurate scholarship, as well as sheer hard work, are shown in the text matter and the comprehensive bibliography of some 700 titles. The results and views of other workers are presented fairly and with judgment. Great use is made of the working hypothesis, an excellent teaching device, but one not to be pressed too hardly. The whole is a model of Gallic scientific exposition—lucid and logical.

Of its uniformly excellent contents space allows special mention of the following only: the clear sensible classification; the skilful treatment of the complicated life-cycles in forms showing alternation of sexuality and agamy; the most useful chapters on precocious parthenogenetic reproduction (pædogenesis), the curious nematode conditions, and plant parthenogenesis.

The two important closing chapters discuss major questions, those of sex determination and evolution. Regarding the former, we may only touch upon the arrhenotokous parthenogenesis peculiar mainly to Hymenoptera and rotifers. The prevalent hypothesis is that males are virgin-born and haploid, while females are sexually-born and diploid. Many new facts, however, show that this interpretation cannot be universally applied, even in Hymenoptera, and raise root problems: (1) Are males really haploid? And (2), if so, why should haploidy spell maleness? The first arises because in cases of natural rudimentary parthenogenesis, and in experimental parthenogenesis, virgin-born organisms as a rule die in early life because their haploid condition inhibits development.

Vandel is sympathetic towards Tauson's findings on rotifers, which suggest that the male is really diploid and shows germ cell haploidy at maturation only, chromosome reduction occurring abnormally early in the diploid spermatogonia. Rotifer cytology being extremely difficult, this new interpretation may be wrong, but even if correct its application may be limited. For, since the publication of Vandel's book, saw-fly studies from the reviewer's laboratory show important features, namely, that the haploid-diploid ratio exists between males and females, while chromosome shape and arrangement suggest the existence of polyploidy and of odd chromosomes which may be sex-determining. Thus we may be within reach of answering the question of haploidy and maleness, hitherto a mystery. The somatic cytology of Hymenoptera will still well repay investigation.

Regarding the evolution of parthenogenesis, the author makes the following points: the parthenogenetic mode of reproduction derives from the sexual; it is very widely spread to a greater or less degree among animals and plants; it has arisen independently in different groups, and the course of evolution likewise differs from group to group.

Certain clues to the origin and evolution of parthenogenesis are seen in the facultative or accidental cases noted in species normally bisexual. The majority of cases are found in Lepidoptera, both sexes being produced (deuterotoky), while female-production (thelytoky), for example, in coccids, is rare. The virgin-born offspring are diploid, and this condition is brought about by different methods of auto-regulation of the chromosome equipment. Now Vandel stresses that among the groups which show rudimentary parthenogenesis there belong those very rare species susceptible to experimental parthenogenesis, and it is therefore deduced that the artificial agencies employed are responsible for the restoration of diploidy, the *sine qua non*, usually, of parthenogenetic development. Hence it seems reasonable to suppose that facultative parthenogenesis is induced by some natural agency or agencies supervening in rudimentary parthenogenesis to bring about the diploid (and viable) state. Of these natural agencies we can say very little.

Direct evidence of the possible origination of parthenogenesis only exists in moth hybridisation experiments first made by Harrison, where the hybrid offspring of two bisexual and non-parthenogenetic species were parthenogenetic. Vandel's alternative interpretation is that this is really a case of facultative parthenogenesis. Only further work will clear the matter. The hypothesis of Winge and Ernst of the hybrid origin of plant parthenogenesis is, of course, not new, and although the proofs are not direct, the many features shared in common by hybrid plants and parthenogenetic plants, particularly polyploidy, strongly warrant such a hypothesis. Vandel stresses another suggestive idea: as polyploidy is intimately associated with geographical parthenogenesis, it may be a cause of parthenogenesis. But of how polyploidy has originated there is no evidence. Parthenogenetic races have been derived by three main mechanisms : (1) a bisexual form has given origin to two types of parthenogenesis, as where thelytoky and arrhenotoky co-exist, for example, saw-flies, or where obligatory thelytoky and facultative parthenogenesis co-exist, for example, coccids ; (2) a heterogonous and migratory species, as among aphids, may have become continuously parthenogenetic owing to the absence of one of the hosts ; (3) a bisexual species may have produced a parthenogenetic race of different chromosomal (polyploid) constitution, for example, in geographical parthenogenesis. Briefly, new species are in the making, and as further proof there is a physiological *amixie* between daughter and parent species. Thus the evolution of parthenogenesis is bound up with the evolutionary rôle of the phenomenon.

There can be no longer any doubt that reproduction solely by parthenogenesis exists, as among rotifers, crustaceans, Hymenoptera, aphids, and all geographically parthenogenetic species. Hence the faculty is of survival value. Further, that parthenogenesis does not lead to stereotypy is abundantly manifest from the mutations observed.

Its widespread distribution suggests strongly that the parthenogenetic faculty, though it may be latent, is a fundamental vital phenomenon capable of being activated under certain conditions. This leaves us with the query: Do absolutely nonparthenogenetic organisms really occur ?

A. D. PEACOCK.

Agricultural Entomology.

A Textbook of Agricultural Entomology. By Dr. Kenneth M. Smith. Pp. xiii + 285. (Cambridge: At the University Press, 1931.) 12*s.* 6*d.* net.

IN this book the author has restricted himself to the treatment of insect pests of the farm, to the exclusion of fruit insects. By way of introduction, Dr. Smith briefly discusses the current methods of insect control and their application to farm practice, namely, insecticidal or chemical, cultural, biological, and legislative. The relationship of insect outbreaks to weather conditions is illustrated by reference to several well-known species. For example, the diamond back moth becomes abundant in hot dry seasons and decreases in wet cold weather. The pale western cutworm (*Porosagrotis orthogonia*) is subject to similar fluctuations, but for an entirely different reason, which the author does not explain on p. 13. The prevalence of heavy rains in the months of May, June, and July constrains this North American species to abandon its subterranean workings and emerge on the surface, when it is then an easy prey to its parasites. The result is a decided diminution of its numbers the following year. So noticeable is the effect that a close study of the meteorological conditions is important in the forecasting of outbreaks of this species.

The systematic discussion of the insect pests themselves occupies ten chapters. They are distributed among eight orders, which, with the families concerned, are briefly defined. Detailed descriptions of the known stages of each species are supplied, followed by an account of the life-history, the list of food-plants and injuries, distribution of the species, modes of control, and the natural enemies that have been recorded in the various countries of the host insect's occurrence.

On the whole, the insect pests of live-stock have received their due share of attention. It is observed, however, that the order Anoplura (not Anopleura) is but scantily noted, and the Mallophaga are not even mentioned. The Siphunculata are classified as sub-order 2, leaving one to imagine what sub-order 1 may be. If *Hæmatopinus suis* is sufficiently important as to receive a whole page to itself, there appears to be no good reason why *H. eurysternus* and *H. macrocephalus* should not have at least been mentioned. Similarly, *Trichodectes* and *Menopon* are of sufficient economic importance as to merit attention. Of other live-stock pests, the warble and bot flies, blow flies, horse-flies, and Hippoboscidæ are adequately treated, and the author is to be commended for bringing his account of the British Œstridæ up to date in conformity with recent researches.

The rôle of insects in the transmission of virus diseases of cultivated crops is a comparatively recent discovery, in the development of which the author has taken an active share. In Great Britain the potato and hop are subject to attack, and the sugar-beet in Germany. The points emphasised are: (1) the vector insect becomes infected when feeding on an infected plant ; (2) the virus remains infective in the insect's body for several days, during which it may infect an unlimited number of susceptible plants ; (3) certain varieties of both cultivated and wild plants may act as reservoirs of the virus without their being themselves adversely affected ; (4) certain plant viruses seem to have an affinity for particular vectors, as for example *Myzus persicæ* (Aphididæ) and the various forms of potato virus. In this new field of study there is opportunity for extensive research, which should be productive of important results.

At the end of each chapter there is given a list of reference literature for the use of those who may wish to tap the sources of information. In the first of two appendices following the last chapter, the author has tabulated for ready reference the characteristic symptoms of insect attack on cultivated crops; in the second he has listed the common farm weeds that serve as alternate hosts for many insect pests of the farm. In the tracking of any species discussed in the book the reader will find every assistance in the three indices, the first of which is authors, the second parasites and predators, and the third general.

It is evident that Dr. Smith has spared no pains in producing a book which will at once be very useful to student and teacher as well as to farmer. The illustrations, seventy-nine in number, are clearly and attractively reproduced. If one would offer criticism, it would be that they might well have been increased with advantage to the explanation of the textual descriptions of species. One also notes the lack of keys to aid the identification of the species discussed. Although most keys are admittedly arbitrary, nevertheless both teacher and student find them very helpful in taxonomic work. It is to be hoped that these suggestions will receive attention and be incorporated in the next edition, which should soon be required. A. E. CAMERON.

Researches on Fungi.

Researches on Fungi. Vol. 4: *Further Observations on the Coprini together with some Investigations on Social Organisation and Sex in the Hymenomycetes.* By Prof. A. H. Reginald Buller. Pp. xiii+329+4 plates. (London, New York and Toronto: Longmans, Green and Co, Ltd., 1931.) 21*s.* net.

PROF. BULLER'S "Researches on Fungi" is well known to mycologists. The first volume appeared in 1909, the second in 1922, the third in 1924. The present volume is divided into two parts. The first of these may be regarded as a continuation of the previous volume, for it is concerned with the further study of the types of fruit-body of the genus *Coprinus*. Eleven subtypes of fruit-body organisation are distinguished by the author, six non-*Coprinus* (Æqui-hymeniferii) and five *Coprinus* (Inæqui-hymeniferii). Nine of these had been described in detail in the two previous volumes, leaving the *curtus* and *plicatilis* types for the present one. Both these types contain only one species. These are set out with precision, though probably most mycologists will be content with reading the summary. *Coprinus plicatilis* is noteworthy in that it does not undergo autodigestion in the manner of the other species, to which they owe the popular name 'inky cap', though the spores ripen and are discharged as in other Coprini. An interesting point about *C. curtus* is that its fruit-bodies may be rendered sterile by fumes from fresh horse-manure.

The relative efficiency of the *Coprinus* and non-*Coprinus* types of fruit-body organisation are discussed. In such comparisons, however, which are based on a comparison of the nicety of the mechanisms which enable the millions of spores produced to be dispersed effectively, it should not be forgotten that this merely means their ability to leave the hymenium. The details of the processes are known chiefly through Prof. Buller's researches, and they are obviously so efficient that the ultimate spore wastage is all the more startling.

Among other points treated in this section are: the well-known *Coprinus* 'ink' used by Bulliard more than a century ago and recommended by Boudier for documents where forgeries might be attempted—the late Prof. G. H. Bryan suggested its use for spotting negatives; the fact that *Coprinus lagopus* is the species which grows on beet and mangel seeds, and that passage of the spores down the alimentary canal of a horse is an essential feature in the life-history of *C. sterquilinus.* The last-named species when growing is able to exert an upward pressure of nearly half a pound—it is the much more robust *C. atramentarius,* however, which so frequently causes surprise by appearing on hard tennis courts and asphalt paths.

The second section of the volume deals with social organisation and sex. A general consideration of social organisation throughout organic beings seems an unnecessary introduction to the well-known fact that the hyphæ of Hymenomycetes fuse on coming into contact and that such a compound mycelium acts as a unit in producing fruit-bodies. The biological advantages of these multiple fusions are stressed, but the experimental evidence that it is mainly nutritional is insufficient.

The problems of sex in the Hymenomycetes have always aroused interest. We seem to be approaching a clearer understanding of the phenomena, but much remains to be done before the facile interpretations of some writers can be accepted. From the time of Sir John Hill until the eighties of last century, sexual organs were discovered by enthusiasts at appropriate stages in the life-history of mushrooms and toadstools; Dangeard's discovery in

1895 of a nuclear fusion in the basidium seemed for some time to alter the focus, and attention was then paid to the origin of the binucleated condition of the mycelium which provided the fusing nuclei. Mlle. Bensaude (to whom the present volume is dedicated) startled the botanical world when she published her account of heterothallism—two different kinds of mycelium necessary for the formation of fruit-bodies—in a species of *Coprinus* in 1918, and showed the significance of clamp-connexions.

Since that time, research has been steadily carried out, and Basidiomycetes, from being more neglected in academic circles than were Fungi Imperfecti, have almost become laboratory pets. Prof. Buller and his pupils have played a prominent part in unravelling the conditions in *Coprinus*. The account he gives here is based on these researches. As, however, these for the most part have already been published, there is not here the stimulus of novelty, though there is a clear account of present facts and theories of heterothallism in Hymenomycetes. The more recent of the author's own researches were summarised in NATURE of Nov. 1, 1930, pp. 686-689.

Prof. Buller regards the phenomena of heterothallism in *Coprinus* and its allies as those of sex. (It is to be noted that heterothallism occurs in all fungal groups and that scarcely a week passes without an addition to the list of species.) The basis for the belief is the fusion of two nuclei in the basidium. It is obvious that this fusion is secondary and that the fusion of different mycelia is not the same as the fusion of sexual organs. Further, four different spores of different sex occur on a single basidium in such a species as *Coprinus lagopus*, and there may be geographical races which are intersterile. It is obvious that the study of these fungi will bring about a change in our ideas of sexuality.

The book is well printed and has a full summary and a good index. The illustrations are almost unnecessarily numerous and the text somewhat prolix, though perhaps this will not be disadvantageous to non-mycological readers. The volume is sure to find a place on the shelves of most mycologists.

General Stratigraphy.

General Stratigraphy. By Prof. J. W. Gregory and B. H. Barrett. (Methuen's Geological Series.) Pp. xii + 285. (London: Methuen and Co., Ltd., 1931.) 10*s.* net.

IN the preface, the authors state that "the international spirit is as necessary in Geology as in Politics". Undoubtedly, geological science cannot afford to be parochial in its outlook, though few geologists can hope to attain the world-wide experience of Prof. Gregory. The study of geology, however, should, like charity, begin at home, and unless a student is in possession of practical knowledge concerning the geology of his own country, he is not likely to profit by reading about the stratigraphical problems in lands beyond the seas.

To meet this need, the general scheme which is followed by Prof. Gregory and Mr. Barrett is to describe British rocks first, and then to give a brief account of their equivalents in other parts of the world. The facts concerning the distribution of land and sea during each geological period are set forth in a number of diagrammatic maps, and an appendix which gives a list of stratigraphical names employed in different countries might help the reader to a clearer understanding.

It must be confessed, however, that the book is disappointing. The compressions and omissions necessary to summarise the main facts concerning the geology of the world within the limits of 239 pages were bound to be unsatisfactory; the result is geological pemmican of a kind scarcely suitable for the student or general reader. Unfortunately, too, the book is marred by defects arising from the exclusion of important matter. Take, for example, the chapter devoted to the Carboniferous rocks. No mention is made of the occurrence of marine bands in British Coal Measures. These are of the highest practical importance for correlation purposes. Again, no account of the Millstone Grit of England is given, nor is any notice taken of the notable researches of Bisat, Wright, and others who have done so much to solve the stratigraphical problems of this formation which had so long defied the efforts of older geologists. Had the authors of this book appreciated the significance of zonal studies, they would have at once realised the misleading character of their statement that zone *S* [of the Lower Carboniferous] was represented by Millstone Grit in the Forest of Dean and that the formation began earlier in the Clee Hills.

Further, one is told that "as the arid climate which brought coal formation to an end began earlier in Scotland than in England only the lowest of the four divisions [the Lanarkian] of the English Coal Measures is represented in the Midland Valley of Scotland", whereas, as has been clearly demonstrated both by plants and shells, the four divisions (if there are four) have representation in the Scottish coalfields. Indeed, it has been shown that the Lanarkian, as originally defined by Kidston, includes rocks which range in age from the zone of

Carbonicola ovalis up to the zone of *Anthracomya pulchra*, and it has been placed beyond all reasonable doubt that Skipseys Marine Band is the Scottish equivalent of the well-known Mansfield bed. The statement "according to his [Hind's] identifications the fresh-water lamellibranchs in one seam at Shettleston, near Glasgow, include those of the three lowest of the six Coal Measure zones of the English Midlands established by Trueman and Davis" (*sic*) cannot be checked in the absence of a reference; while recent work on the Coal Measures lamellibranchs in the Scottish coalfields confirms the value of the zonal studies initiated by Dr. Trueman and his co-author, and successfully applied by numerous workers in British coalfields. In regard to the Barren Red Measures of Scotland which have been proved to fall within the zones of *Anthracomya phillipsi* and *A. tenuis* in Ayrshire, no mention is made of them, but the passing reference to their equivalents in Lanarkshire in the chapter devoted to Permian rocks is, to say the least, not helpful.

The reference to the succession in the Kent coalfield is also faulty. Neither Lanarkian rocks nor Lower Carboniferous beds of Pendleside facies are present; on the contrary, Coal Measures of Yorkian age rest with marked unconformity on Lower Carboniferous Limestones. Nearly every reference to South Wales in this chapter and throughout the book is definitely erroneous.

It is decidedly unfortunate that the printer's imp has been unusually busy. Some of the errors of spelling are harmless, but others are likely to mislead the reader. To mention one: *Cœnograptus* is quoted as a Cambrian graptolite. It seems a pity that the book, the compilation of which must have entailed an immense amount of labour, should have so many blemishes, but one may hope that in a second edition most of these will have disappeared. J. P.

The New Surveying.

Surveying from Air Photographs. By Capt. M. Hotine. Pp. xi + 250 + 8 plates. (London: Constable and Co., Ltd., 1931.) 30*s.* net.

It was chiefly due to the War that surveying from air photographs emerged from the state of being an ingenious but not very serious or practical method, into the condition of being in certain cases indispensable and in many cases of genuine value, and, it may be added, in all cases to be reckoned with. The history of the method ante-dates the invention of aeroplanes. It had been used with comparative success from balloons; and, in the British service, it was the late Col. Elsdale who developed the use of small free balloons, which travelled a sufficient distance to allow a series of plates to be exposed, and then upset themselves and came down to the ground. Photographs of this kind were taken so long ago as 1885.

Since then, as we all know, enormous progress has been made, and those who desire to learn the present condition of this up-to-date art cannot do better than study the admirable volume by Capt. Hotine which is here under review. From the author's preface we shall learn that the object of the book is to describe the way of constructing a map, plan, or detailed description of any portion of the earth's surface by the use of photographs taken from the air. The various chapters deal with such branches of the subject as the general characteristics of air photographs, their interpretation, their economic uses, and such matters. But the bulk of the book is, of course, taken up with discussion of perspective problems, surveying cameras, and, above all, with the employment of stereoscopic methods. In fact, it may be said that the chief change that has taken place in recent times has been the increasing use of the stereoscope for the measurement and interpretation of pairs of photographs taken in the air at short intervals of time.

We are early introduced to stereoscopic pairs, air bases, overlaps and time intervals, lateral and forward obliques, strips, and such details, all very clearly explained. The difficulties inherent in the method are not ignored; for example, the author remarks that at present "the problem of obtaining an accurate measurement of level during flight must be considered as definitely unsolved". In the same way, he points out that aeroplanes cannot, for surveying purposes, be flown economically on courses which are generally north and south. He points out, also, that there is a difficulty in interpreting the features of the ground and in identifying objects, because, at a great height, the landscape appears almost monochromatic. This leads to the dictum that much is to be lost by attempting the interpretation of single photographs; "it is a safe rule to use the stereoscope on all occasions".

Valuable information is given as to the scales that can be economically used for maps constructed from air photographs. The conclusions are that the largest scale is about 1 : 2000, that is, about 30 inches to the mile. The smallest scale which the method can produce is about 1 : 30,000, that is, about 2 inches to the mile. Very large scales and very small are equally unsuitable. The small scale above mentioned involves the use of a 7-inch lens at a height of 18,000 feet.

An interesting section is devoted to the description of the Canadian 'grid' method, in which high, oblique, single photographs are employed; each photograph shows the visible horizon near its top edge; this horizon line, corrected for curvature and refraction, is used as a line to measure from, and a suitable standard, perspective, straight-line grid is superimposed: the plan can then be drawn by simple rectification of the oblong spaces of the grid—an eminently simple and practical device for the mapping of a flat country like much of the territory of that great Dominion. These photographs are taken with a bare minimum of ground control, from a height, as a rule, of 5000 feet.

This case must, however, be looked upon as exceptional. In general, stereoscopic methods would nowadays be employed. In addition to more certain identification than single photographs can give, the method provides a means of fixing relative heights and of contouring. Much space is rightly devoted to an account of stereoscopic methods and instruments. Descriptions of instruments are always difficult to follow without constant reference to the instruments themselves, and it is no slur on this admirable book to say that these sections will be of special value to the student who has the instruments at hand for reference.

Mathematical sections deal with perspective and the theory of mapping from stereoscopic pairs. Some of this is rather difficult reading—from the nature of the case—and it may, perhaps, rather frighten the 'practical' man. It might have been relegated to an appendix. However, as the author remarks in his preface, the reader who mainly desires to learn practical methods can, if he likes, skip all the mathematical chapters, without losing anything of practical application. The book is, indeed, a very thorough piece of work, and is an indispensable textbook of modern practice in the application of air photography to surveying. This application is by no means so simple as might appear at first sight, and if anyone should think that he could conduct an air survey by the light of Nature, without considering past theoretical studies and practical experience, a reference to this book should go far towards undeceiving him.

C. F. C.

Viscometry.

A Monograph of Viscometry. By Dr. Guy Barr. Pp. xiv + 318. (London: Oxford University Press, 1931.) 30*s*. net.

THE author begins his preface by commenting on the striking disproportion between the small number of works devoted to the subject of viscosity and the enormous number of papers which deal with one or the other of its aspects. Such books as there are give a limited space only to methods of measurement, and the author has felt "that there was need of a book devoted entirely to viscometry, in which an investigator would be able to find some account of most of the schemes which have been applied and some indication of the theoretical and practical difficulties that affect each of them".

Such a book has certainly been lacking, and the author has been completely successful in supplying it and in filling a curious lacuna in the literature of physics. After a brief introductory chapter dealing with fundamental concepts and historical development, he proceeds to develop very fully the theory of viscous flow through cylindrical tubes, and of the corrections which have to be applied in deducing viscosity coefficients from measured rates of flow. Three chapters are devoted respectively to tube viscometers for absolute measurements, commercial absolute viscometers, and capillary viscometers for relative measurements. The treatment is extremely complete: all the conditions to be satisfied and corrections to be applied are set forth clearly; the reader will certainly, as the author suggests, get the impression that absolute viscosity measurements in the strict sense present "a problem calculated to tax the resources of the best equipped physical laboratories". His relief at finding that nowadays relative determinations will generally be adequate may be tempered on reading the chapter describing the instruments for this purpose, and on discovering that many precautions and corrections are necessary which have been neglected in the numerous investigations carried out with the—all-too-convenient—Ostwald viscometer.

The commercial viscometers are classed as 'absolute' because "their standardisation depends in the first place on dimension", although, in practice, calibration is generally necessary. They are treated as fully as the laboratory instruments with long tubes, and standard specifications of the Redwood, Engler, and Saybolt instruments, as well as conversion tables, are given in appendices.

A chapter is devoted to the transpiration method of determining the viscosity of gases; the equations for a compressible liquid, for which the pressure gradient is no longer constant, are deduced, and various types of apparatus described in detail.

Flow between parallel plates, which is rarely mentioned in the literature of viscosity, also receives attention. As the basis of a method of measurement, it shares with the concentric cylinder system the inconvenience that, while the mathematical treatment is simple for infinitely extended pairs of surfaces, the introduction of boundaries, necessary in practice, causes serious complications.

In the discussion of the falling sphere method, the corrections to Stokes's formula introduced by Oseen and the more recent work of Faxen are fully considered. The method is perhaps the most striking instance of the restrictions imposed by purely technical factors on the practical application of a theoretically simple procedure: in this case, the difficulty of obtaining accurate spheres other than the steel balls used for bearings.

"Rotational and Oscillational Viscometers" include many types which have been used occasionally only: for example, the circular disc oscillating in its *own* plane in Maxwell's classical investigation on the viscosity of gases, and in some early work on the variable viscosity of colloidal solutions. The various types of concentric cylinder instruments, which alone have found somewhat extended use, are all described and discussed fully.

The book concludes with a chapter on "The Study of Anomalous Systems", in which the peculiarity of disperse systems, namely, a decrease of the viscosity coefficient with increasing velocity gradient, and the instruments designed specially for studying it, are briefly but adequately described. The author unavoidably touches on the question whether a special name is required for this property and seems to favour "apparent viscosity". He remarks in this connexion: "The early successes of Bingham's hypothesis of plastic flow led many workers to adopt the term plasticity to distinguish the property in question, both of lyotropic sols and of suspensions, from the viscosity of normal liquids". This practice was almost entirely confined to the United States, where many systems were described as 'plastic', the published flow-pressure diagrams of which certainly do not conform to Bingham's fundamental assumption; in a few years the term will presumably go the way of 'colloidal behaviour', which at one time was so widely borrowed from J. Loeb.

The author has made an admirably complete selection from a peculiarly scattered literature and has presented it critically and lucidly. It deserves to be widely read, and while it is too much to hope that everybody who has to make viscosity measurements will study it with due care, it may induce a few workers to carry them out with the necessary care and precautions—or to refrain from publishing them.

The printing and illustrations conform to the general high standard of the publishers, and proof-reading has been done with exceptional care.

EMIL HATSCHEK.

Nature of Chemical Forces.

Radioelements and Isotopes: Chemical Forces and Optical Properties of Substances. By Kasimir Fajans. (The George Fisher Baker Non-resident Lectureship in Chemistry at Cornell University, Vol. 9.) Pp. x+125. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1931.) 12*s.* 6*d.* net.

PROF. FAJANS' Cornell lectures form a very small volume in comparison with those provided by former holders of the Baker lectureship, since they cover only 113 pages of text. The reason for this is a wish to avoid republication of material which is already in print. Thus a course of lectures on radioactivity and isotopy has been omitted, because these subjects are dealt with in existing books by the author and others; but one of the most interesting of current problems is discussed fully in a chapter on the origin of actinium. The conclusion is drawn that this element has an atomic weight of 227 and must, therefore, be entirely distinct from the radium and thorium series, where all the atomic weights are *even*, thus giving rise to radium lead, Pb^{206}, and thorium lead, Pb^{208}, which have both been separated in an almost pure state from minerals rich in uranium and thorium respectively. Strong confirmation of this conclusion is supplied by Aston's observation that lead actually contains the third isotope, Pb^{207}, and we may, therefore, now accept also the further deduction that actinium has its origin through protactinium in an odd-numbered isotope of U^{238}.

Apart from the twenty-four pages occupied by his interesting chapter, the book contains an introductory lecture on "The Development of Views regarding the Nature of Chemical Forces", and seven chapters on "Chemical Forces and Optical Properties". These chapters are naturally devoted in the main to a summary of the author's experimental work on the refractive indices of crystals of the alkali halides and related substances as evidence of the deformability of ions, but they also contain the arguments which he uses as evidence of the existence of transitional states between the ionic linkage, which is the common type in mineral salts, and the non-ionic linkage of organic compounds.

Arguments based on the feeble electrolytic conductivity of fused halides, such as aluminium chloride, carry little or no weight, since intermediate degrees of conductivity between those of fused sodium chloride and of liquid carbon tetrachloride must be expected in all those cases in which a covalent complex undergoes reversible ionisation. A more plausible argument can be based upon the difficulty of determining the type of linkage in compounds such as zinc sulphide and silver iodide, which crystallise on a diamond lattice, since it is not easy to admit that the reversible ionisation of covalent bonds is a normal state of affairs in a crystal; and at the absolute zero this process appears to be impossible. The argument is weakened, however, by including gaseous hydrogen chloride amongst the transitional compounds, since it is obvious that the proton cannot persist as a free ion, but must be enveloped by the planetary electrons of the halogen, thus giving rise to a definitely covalent compound. It differs from gaseous hydrogen, however, in the readiness with which (by reason of the stability of the octet of the chloride ion) the proton can be transferred to a molecule of water.

A similar condition appears to exist in stannic chloride, which has all the attributes of a covalent compound, until it is dissolved in water, when it is ionised reversibly, perhaps by co-ordination with the solvent as indicated by the equation:

$$SnCl_4 + H_2O \rightleftharpoons [SnCl_3{\cdot}OH_2]^+ + Cl^-.$$

Whilst, therefore, the *absence* of intermediate forms of linkage may still be open to question, more evidence appears to be required before their *presence* can be regarded as established.

The two concluding chapters deal with the adsorption of ions on salt-like crystals, with applications to volumetric analysis and to photochemistry. These applications have a direct practical value; but the theories on which they are based and which they serve to illustrate are also of fundamental importance, since the obscure notions of electrical double-layers, which were both puzzling and repulsive to students of a former generation, become both simple and clear when discussed in terms of an unequal distribution of ions of opposite signs. The book will therefore be read with interest, not only by those who had the privilege of hearing the lectures delivered, but also by many others who will be glad to have the most important of their contents set out in so concise a form.

Paper Making.

The Digestion of Grasses and Bamboo for Paper-Making. By W. Raitt. Pp. xi + 116 + 20 plates. (London: Crosby Lockwood and Son, 1931.) 21*s*.

THE rapid expansion in the demand for paper and for newsprint consequent on the spread of education, as well as the habit of wrapping everything up in several coverings of paper or cardboard, is a fact which, besides its special significance as an index of progress, causes concern to those who have to find new raw materials for the paper-maker. Commencing in the period of intellectual revival after the Napoleonic wars, when the consumption of paper per head in Great Britain was only an ounce or so per annum, the demand has continued until to-day it has been estimated at more than 70 lb. a head.

In America the consumption is still greater, and the world's annual requirements are in excess of twenty million tons. The English Education Act of 1870 is said to have multiplied consumption by ten within ten years. Little wonder that the demand has outstripped the supplies of raw materials, at first of rags and then of cereal straws first introduced in 1860. Esparto came to the rescue in 1860, but the economic radius of its collection was reached thirty years ago, and the production since has been very regular. Wood pulp first appeared about 1866–70 and has held the field until now, during a period in which a large part of the world's timber resources has been cut, so that to-day great anxiety is expressed for future supplies. The annual cut in the United States is four times the annual growth; in Canada only some twenty-five per cent of the original forest wealth is left. Obviously, if the expansion in demand continues, as it will, for cellulose has become a raw product of so many other industries, in particular artificial silk, which has almost unlimited potentialities, new sources of supply will have to be found.

It is obvious that trees are too slow growing to maintain supplies; some pulp wood is a forty years' crop; twenty-five to thirty years is required in Canada to bring a spruce tree to pulp wood size, though in the south with the loblolly pine it is now said to be possible to grow pulp wood in ten years.

The future obviously lies with the grasses, particularly the bamboo, if once satisfactory pulp can be obtained from it. In the past, troubles were experienced in the digestion and bleaching of bamboo cellulose, mostly because the work had been carried out empirically, without the scientific assistance of the chemist, and it is largely owing to the systematic work of Mr. Raitt that these difficulties have been overcome.

For twenty-five years, in part assisted by the Government of India, Mr. Raitt has made an exhaustive and scientific study of the subject, with the result that the problem of the utilisation of the bamboo has been largely solved. Culms of all ages, including the nodes, can be digested, mixed together, with a soda consumption of 16 per cent on the weight of bamboo, and a bleaching powder use of 8 per cent on the pulp at a pressure of 30 lb. of steam, the process only taking 5 hours. A yield of 45 per cent of unbleached and 42 per cent of bleached pulp is obtained by this process.

The book under review is a complete epitome of the subject based on Mr. Raitt's own practical experience; it deals with the analysis, the digestion in the autoclave, and all the practical problems arising out of the treatment in large scale operations, and contains an attractive account of the occurrence and growth of the bamboo. A section devoted to the microscopic features is illustrated with twenty plates.

The world's total standing crop of bamboo is enormous. In Burma alone an annual crop of 150 million tons is talked of, much of which could be easily exploited commercially, so that if suitable pulp really can be made from it, a supply which is inexhaustible can be obtained from materials which have no value for any other purpose.

E. F. ARMSTRONG.

The Teaching of Mathematics.

Craftsmanship in the Teaching of Elementary Mathematics. By F. W. Westaway. Pp. xvi + 665. (London and Glasgow: Blackie and Son, Ltd, 1931.) 15*s.* net.

SOME four hundred pages of this book are given to the elementary parts of mathematics, from the first four rules of arithmetic up to the standard of a school certificate. The treatment is varied, but often takes the form of outlined specimen lessons; it is full of useful hints about the details of teaching, and is sure to be welcomed by a large body of teachers.

Mr. Westaway's attitude is that of a moderate reformer. He is very far from wishing to impose stereotyped methods on teachers: so much so that sometimes a piece of good advice is given with insufficient emphasis—for example, "it is doubtful if the term infinity ought to be used below the Sixth". What he cannot abide is the slavish adoption of doubtful forms of traditional procedure. His standard of what a boy ought to know is very high; we read, for example, that fourth form boys are prone to forget the factors of $a^4 + a^2b^2 + b^4$. The excursions into logic are not very successful, though there will be general agreement with what is said about its restricted place in elementary teaching.

In spite of such blemishes, the book will undoubtedly be of great value to the inexperienced teacher; and not to him alone, for there is much that will be helpful to the master responsible for organisation. The importance of the teaching of the lowest sets is insisted upon, and there are useful suggestions about the non-specialists in the sixth form. There are interesting chapters on wave motion, map projections, and statistics, and some shorter ones on subjects like astronomy and optics; these will serve to remind the organiser of some topics that are often neglected.

Mr. Westaway's experience of the teaching of mathematical specialists would seem to have been unfortunate. He has sometimes been "almost bored to tears . . . with the petrifying stuff doled out . . . which is virtually the same as forty years ago". The development of calculus teaching with its applications to mechanics, the improvements in analytical methods and the freer use of projective methods in geometry, and the mitigation of 'identity' work in algebra and trigonometry, are a few indications that specialist teaching is not, as Mr. Westaway seems to think, being stabilised at the level of 1890.

Thus it may be expected that the specialist part of the book will be less valuable than the other. There are, it is true, still useful hints to be found, but the material and treatment smack of the nineteenth century rather than of the twentieth. For example, the "principle of continuity" is quoted from a textbook that appeared in 1893, and although we are told that pupils must understand the notion of a limit, we find, elsewhere, the archaism "when Q coalesces with P, the angle becomes a right angle". Again, the Argand treatment of complex numbers is prefaced by the reactionary proposal to "define the symbol $\sqrt{-1}$ as an expression whose square is -1".

Many references to other books are given, and there is an interesting questionnaire for young teachers which will tax the powers of many of their seniors.

Short Reviews.

Anthropology and Archæology.

Early Man: his Origin, Development and Culture. Lectures delivered for the Royal Anthropological Institute. By G. Elliot Smith, Sir Arthur Keith, Dr. F. G. Parsons, M. C. Burkitt, Harold J. E. Peake, Dr. J. L. Myres. Pp. xii + 176 + 12 plates. (London: Ernest Benn, Ltd., 1931.) 8*s.* 6*d.* net.

In 1929 the Royal Anthropological Institute inaugurated courses of open lectures of a popular character, of which the first series dealing with early man, delivered in the winter session 1929–30, is published in this volume. Of six lectures in all, three deal with the origin and descent of man from the point of view of the physical anthropologist, and three with aspects of the beginnings of culture. Of these latter, that by Mr. Miles Burkitt on "Most Primitive Art" is printed in abstract only, but compensation for the lack of a fuller development of his demonstration of the method of study by 'art groups' is forthcoming in the examples from French and Spanish caves and from South Africa, which have not been published previously.

On the physical side, Prof. Elliot Smith deals with the origin of man. Happily for his readers, while the volume was passing through the press, he was able to add to the lecture, as originally delivered, his conclusions on the place of Peking man in relation to other relics of early man, based on discoveries afterwards made at Chou Kou Tien. Sir Arthur Keith deals with the evolution of races in the past and in the present, and Dr. F. G. Parsons summarises the anthropological history of the modern Englishman, analysing the physical characters of different racial types that have gone to the make-up of that remarkable hybrid.

Of the remaining two lectures dealing with early culture, Mr. H. J. E. Peake on the beginnings of agriculture summarises the present position of research on the origin of cultivated grains, with special reference to wheat and barley, and discusses its bearing on the problem of the antiquity of civilisation in Egypt and Mesopotamia. The course of lectures closed with Prof. J. L. Myres's lecture on the discovery and early use of metals, which appears here in much extended form. Of two chapters, one deals with the 'precious' metals and the second with the 'useful' metals, with a wealth of illustration and commentary which ranges widely over the whole field of early culture and belief. The lecture is as delightful to read as it is informative.

Index of Potters' Stamps on Terra Sigillata "Samian Ware". By Dr. Felix Oswald. With a Supplement (to be consulted in conjunction with the Index) of Stamps obtained or recorded during the Period of printing the Index (with Corrections). Pp. xxiii + 428. (East Bridgford, Notts.: The Author, Margidunum, 1931.) 36*s.*

Dr. Felix Oswald's index to the potters' stamps on Terra Sigillata is an achievement in more senses than one. Owing to the difficulty of obtaining a publisher for a work of so highly specialised a character and the expense of private publication, the author has himself set up and printed the whole on a hand press. It has been the work of his leisure over a period of three years. The result is a credit to his knowledge of typography; and students of Roman provincial cultures are doubly indebted to him for carrying to completion this laborious but indispensable task, by which he supplements and completes the study of sigillata ware published by him in collaboration with Dr. T. Davies Pryce eleven years ago.

With the supplementary list of marks which have accrued in the past three years while the main body of the work was being printed, Dr. Oswald has now brought the list of potters' stamps completely up to date; but he has also added to the stamps previously published in the lists in the corpus of inscriptions, which goes up to 1906 only, the place and period of the potter and the form of the vessel on which the stamps occur, particulars essential for the archæologist but omitted from these lists. The index itself is of highly specialised interest, but as Dr. Oswald indicates in his preface, an examination of the stamps yields much information broadly of interest to archæologists, such as the movements of trade from Gaulish and German factories, the origin and place of work of the potters, their partnerships and nationalities, and even, in some cases, their personal characteristics.

An Introduction to the Sociology of Islam. By Reuben Levy. (Published for Herbert Spencer's Trustees.) In 2 Volumes. Vol. 1. Pp. viii + 410. (London: Williams and Norgate, Ltd., 1931.) 21*s.* net.

This volume is the first of a series to be published by the trustees of Herbert Spencer's will in continuation of his "Descriptive Sociology". Up to a point, Islam lends itself to the treatment which Spencer planned. Mohammedan communities have common characteristics based on their religion which make it possible to treat them as a unit. That unity, however, is no more than formal, and unless the treatment of the subject is to be allowed to expand to an almost inordinate length, local differences must be ignored, especially in outlying regions, such as Zanzibar and Malaya for example, where earlier custom and animistic belief have coloured practice. Mr. Levy has not passed over such differences entirely, but has been able to refer to them only in selected instances.

In his first volume now published, Mr. Levy, after an historical introduction which sketches the growth of Islam and its territorial extent at various periods of its history, analyses the effect of its religion on the life and organisation of society. He covers the grades of society, the status of the woman and the child, jurisprudence, and the caliphate and central government. The form of government in the independent Islamic provinces, ethics, philosophy, and science are being dealt with in a second volume. Students and others interested in Islam will be grateful for this convenient and compendious survey. Very full bibliographies appended to each chapter serve as a guide to closer study.

Biology.

Journals of Gilbert White. Edited by Walter Johnson. (Broadway Diaries, Memoirs and Letters.) Pp. xlviii + 463 + 4 plates. (London: George Routledge and Sons, Ltd., 1931.) 21*s*. net.

GILBERT WHITE's "Natural History of Selborne", 1789, is a book which stands alone as the work of a charming, kindly old bachelor, naturalist, and poet. It is simple and happy, full of the joy of life, and has a fine literary style of its own; it will probably be for all time the premier work on the natural history of any part of England. The "Natural History" was largely culled from White's *Garden Calendar*, published in full by Bowdler Sharpe in his edition of Selborne, 1900, and from the *Naturalist's Journal*, begun in 1768. The latter is now published for the first time, and it is ably edited, so that passages already used by White are eliminated. But why is it published at all? It was not written by White to be published—and we feel that he would have been very averse from doing so. It adds nothing to White's fame, gives no fresh picture of his life and times, and relatively few natural history observations of value to-day. It was proper to preserve it in the British Museum, but we feel that it would have been preferable to allow it to remain in its honoured obscurity.

An Introduction to Zoology. By P. W. Gideon. Pp. vi + 90. (Dharwar: Students' Own Book Depot, 1930.) 5.8 rupees.

THE title of the present book gives no indication as to its nature. It is really a laboratory guide, which in size and the arrangement of the plates recalls Howes's "Atlas of Biology", and is intended for use in the intermediate science classes of the Indian universities. There are twenty-one chapters, some general, but most deal with a series of animal types, from Amœba to the frog. Each chapter contains a general introduction, one or more plates of figures, and several pages of notes arranged in a schematic way. By means of these notes a very large amount of information is conveyed in a limited compass. Considering that it was printed in a small centre, it is well done, but it contains a number of typographical errors. The drawings are clear and well reproduced. In addition to the usual information regarding the types, there are also classifications of the phyla and main groups to which the different animals belong.

The book should prove useful to the students for whom it is intended, and has much to commend it. The danger lies in the student allowing its drawings and notes to replace his own, and in 'cramming' from it instead of relying upon fuller texts. The author has obviously spent considerable time and thought in planning the work, and it will not only assist the student in the laboratory but also help him to arrange his information and to revise his work.

Flora of West Tropical Africa: the British West African Colonies, British Cameroons, the French and Portuguese Colonies south of the Tropic of Cancer to Lake Chad, and Fernando Po. By J. Hutchinson and Dr. J. M. Dalziel. Prepared at the Herbarium, Royal Botanic Gardens, Kew, under the supervision of the Director. Published under the authority of the Secretary of State for the Colonies. Vol. 2, Part 1. Pp. iii + 292. (London: The Crown Agents for the Colonies, 1931.) 8*s*. 6*d*.

IN part 1 of vol. 2 of this "Flora", thirty-three families of Gamopetaleæ are considered. From the economic point of view none is of very great significance, but botanically speaking there are several of great importance, notably the Rubiaceæ and the Compositæ. These two account for seventy-three and seventy-two genera, and 465 and 192 species respectively. The former has also the most prolific genus in *Psychotria*, which is represented by fifty-two species in this region. Altogether the thirty-three families present 420 genera and nearly 1600 species; of the latter 102 are new, and there are two new varieties and forty-nine new combinations.

The co-operation of Miss M. B. Moss was obtained for the preparation of the Myrsinaceæ and the Loganiaceæ and of Mr. A. Bulloch for the Solanaceæ.

An interesting fact in plant distribution is the considerable number of species common to this tract and to India, especially the south-west of that country. Strangely, however, *Avicennia officinalis* Linn., which is present in the mangrove swamps of India and East Africa, is not found; the genus here being represented by *A. nitida* Jacq.

Plant Physiology: with Reference to the Green Plant. By Prof. Edwin C. Miller. Pp. xxiv + 900. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1931.) 35*s*. net.

IN the preface of this book, which he describes as an advanced text in plant physiology, the author points out that the various European textbooks usually fail to deal adequately with the work of American and English plant physiologists. In this book American and English work is very adequately covered, whilst continental work is by no means neglected.

The field of plant physiology is very well covered; a beginning is made with the cell, the entry of water and solutes are then considered and the loss of water from the plant, metabolism, translocation, respiration, growth. Directional growth responses (tropisms) receive very scant attention. The treatment of every subject is comprehensive and clear and the citations of literature, especially modern work, very full, but little attempt is made at a critical appraisal of this great mass of material which, to many students, may prove bewildering rather than illuminating.

Manual of Bacterial Plant Pathogens. By Charlotte Elliott. Pp. ix + 349. (London: Baillière, Tindall and Cox, 1930.) 22*s.* 6*d.* net.

This volume is the outgrowth of a card-index on bacterial parasites of plants accumulated by the author and is presented in the form of short summaries of the characters of the organisms and of the disease produced, together with remarkably complete bibliographies of each pathogen.

The book is divided into three parts; the first part, which forms three-quarters of the whole volume, consists of a list of all known bacterial pathogens arranged in alphabetical order, the classification adopted being E. F. Smith's modification of Migula's system. The second part comprises a list of organisms described as commonly found in association with pathogens, but not themselves parasitic, while the third part consists of a chart of the chief characters of the organisms arranged in chronological order of discovery. This last would have been of much more use if the arrangement had been alphabetical, as in the body of the text.

As a source of reference, particularly to the literature, the book will prove of great value to all plant pathologists. R. H. S.

Pflanzenmikrochemie: ein Hilfsbuch beim mikrochemischen Studium pflanzlicher Objekte. Von Dr. A. Tunmann. Zweite vermehrte und verbesserte Auflage bearbeitet von Prof. Dr. L. Rosenthaler. Pp. xxiii + 1047. (Berlin: Gebrüder Borntraeger, 1931.) 75 gold marks.

The new edition of this well-known book on plant micro-chemistry has been considerably enlarged under the editorship of Prof. Rosenthaler of Bern.

To the general section of the work has been added a section upon micro-manipulation in which, as also in the description of methods of counting and measuring under the microscope, Dr. Ehlers of Jena has collaborated. Sections are also added upon urea, compounds of uronic acid, vital staining, membrane pigments in the mosses, pigments of fungi and bacteria, etc. The citations of literature in the footnotes continue to be very extensive, and the account in small type, which accompanies the different substances discussed and analyses their distribution in the plant kingdom, also remains a very satisfactory feature of this comprehensive and valuable laboratory reference book.

Physiology.

(1) *Ultra-violet Radiotherapy.* By Dr. W. Kerr Russell. (Modern Treatment Series.) Pp. 130. (London: Jonathan Cape, Ltd., 1930.) 5*s.* net.

(2) *Therapeutic Uses of Infra-red Rays.* By W. Annandale Troup. Pp. viii + 58 + 16 plates. (London: The Actinic Press, Ltd., 1930.) 5*s.* 6*d.* net.

The electromagnetic waves which have found a place in therapeutics extend over a considerable portion of the spectrum, from the γ-rays of radium and the X-rays of short wave-length, through the ultra-violet to the infra-red rays, of long wave-length. In 'light' treatment, the ultra-violet rays play an important part, although their sources used in practice usually emit heat waves also: in 'heat' treatment, the action is due to the long infra-red waves, although the source used may emit visible light rays at the same time.

Light and heat treatment have been employed in a great variety of diseases with benefit in many cases, but as with other kinds of treatment, experience is necessary, and overdosage has unpleasant after-effects. The value of the treatment can only be determined by observation of the results obtained, which depend on the technique adopted as well as on the variable responses of different patients. Hence precise descriptions of technique and the results observed in different diseases are of value in enabling physicians to select those cases which are likely to be benefited by the treatment.

In both the little books before us, the authors describe their technique and their results. Dr. Kerr Russell considers that ultra-violet radiotherapy is almost a specific in certain diseases, and a useful adjuvant to other methods of treatment in many others. Dr. Annandale Troup's book is the first published in Great Britain devoted specifically to the therapeutic uses of infra-red rays; he prefers a low temperature generator, which he describes in detail. The rays are of value in chronic rheumatic conditions, and in sprains and other injuries they can be used in conjunction with ultra-violet radiotherapy.

These books should be of value to those employing this treatment and to others who wish to have some knowledge as to the type of case which it may be expected to benefit.

Bread: a Collection of Popular Papers on Wheat, Flour and Bread. By Harry Snyder. With Biographical Sketch by Andrew L. Winton. Pp. x + 293 + 20 plates. (New York: The Macmillan Co., 1930.) 10*s.* 6*d.* net.

Harry Snyder, who died at Minneapolis four years ago, had many friends and admirers in Great Britain. In the United States he was known as the champion of pure white flour and the outstanding man of science in the milling industry. This book contains a biographical appreciation of him by Andrew L. Winton and a series of papers on bread and cognate subjects which are considered of such value as to be of wide interest.

Snyder's theme was the rightful place of bread in the human diet: his conclusions are as valid to-day as when they were first written. The papers form a most valuable source of information on all that concerns bread and flour and wheat, and they are worth a place on the shelves of everyone interested in preserving this source of our food in a pure state. It is a matter which will always require watchful care; Snyder himself did not a little in attacking fallacies concerning food values which were being exploited by the aid of generous advertising. E. F. A.

Psychology.

The Mental Defective: a Problem in Social Inefficiency. By Dr. Richard J. A. Berry and Dr. R. G. Gordon. Pp. xi + 196 + 8 plates. (London: Kegan Paul and Co., Ltd., 1931.) 8*s.* 6*d.* net.

It is almost impossible for a lay mind to form any conception of the tremendous financial drain on the country's resources caused by the socially inefficient or higher grade mental or moral defective. Dr. Berry and Dr. Gordon have set out, in their book, to give a plain and straightforward account of the various grades of mental defective, so that the lay mind may understand the most difficult of social problems, the elimination of the defective from our midst.

The authors provide us with three preliminary chapters—the two on the evolution of brain and the making of mind being particularly well set out, although it is very doubtful if the most educated layman will understand what the authors mean when they describe the "synaptic junction between the axon of the connectant or internuncial neurone and the dendrons of the effector neurone". The anatomy is really too complicated for a layman. The photographs of the higher-grade defectives give a false impression. It is notoriously difficult to pick out defectives from photographs, if not actually impossible.

The best chapter in the book is that dealing with policy. This chapter ought to be read by all members of county councils dealing with the defective in their midst. The running of model colonies for defectives and, more important still, for border-line cases who are socially inefficient is a step in the right direction, but one which, we feel, will take a long time to penetrate to the right quarter.

Brain and Mind. By Arthur Lynch. Pp. 36. (London: The Pioneer Press, 1931.) 6*d.*

When philosophical conclusions are categorically expressed in the first person, it shows that their author is in earnest. Yet individual convictions, however strong, can scarcely pretend to carry universal assent. Philosophers, in particular, are hardened people: the very history of their subject compels them to be sceptical as to the decisive value of any particular system. To base a philosophical theory on the assertion that "psychology is the matrix of the sciences" is nothing new in itself. Scores of psychological schools are attempting the same thing from various angles; while in the more abstract domain of thought, the Russellian and the Brouwerian interpretations of mathematics and logic, in spite of their conflicting results, have shown some remarkable specimens of analysis of mental processes. The claims of Col. Lynch need therefore strong justification: the position of their author will be much clearer if he himself confronts his conclusions with those of other schools of thought. Otherwise an unassuming critic is bound to find in them some vague reminiscences of earlier readings. T. G.

The Will to Live: an Outline of Evolutionary Psychology. By J. H. Badley. Pp. 267. (London: George Allen and Unwin, Ltd., 1931.) 10*s.* 6*d.* net.

The author gives us what he considers is a useful dissertation on psychology in general, suitable for boys and girls who have just left, or are about to leave, school. We think a better title might have been chosen; comparatively few children of school-leaving age show any great interest in 'the will to live', but might be very interested in modern points of view in psychology simply told. The book is very well laid out and, generally speaking, presents a very readable account of psychology. We should prefer to see the word 'complex' used in its narrower meaning; in ninety per cent of cases when the word complex is used in modern psychology it refers to what the author would prefer to term a 'buried complex'. We think the author might have given a rather fuller account of Adlerian theories, for they appeal considerably more to the lay mind as a distinctly healthier view than either those of Freud or even Jung.

Agriculture.

Principles of Tropical Agriculture. By Dr. H. A. Tempany and G. E. Mann. Pp. 328 + xxiii. (Kuala Lumpur: The Incorporated Society of Planters, Malaya, 1930.)

Most books published in English on agriculture in the tropics seem to assume that the greater part of the tropical zone has a high and constant rainfall, and that the so-called 'planting crops' form the chief agricultural enterprises in the hotter parts of the world. The result is to give a very unreal picture of tropical agriculture. The present book is no exception to this rule. It has been written as a textbook of general principles to be taught to students in Malaya. For this purpose it is, on the whole, very well suited, for the conditions with which it chiefly deals are those found in this typical wet tropical area. On the other hand, the portions dealing with the far more frequently occurring dry tropical conditions are very perfunctory, and it is doubtful whether the book should be recommended to a student whose future interest is likely to lie in such areas.

One at least of the authors has had very wide experience in the West Indies, Mauritius, Java, and Malaya, and hence, naturally, the chief tropical data cited are from these areas. It is rather a pity, however, that these have not been supplemented to a greater extent from the work done and information obtained in West and East Africa and, particularly, in India—especially as regards soil conditions and manurial methods found useful there, even with the type of crop and condition with which the book chiefly deals.

For the narrow purpose for which it has been chiefly written, the book will probably be found of great use, and an advance on anything hitherto available; but as a general manual of the principles on which tropical agriculture is based it will be found of comparatively little service. H. H. M.

The Culture of the Orange and Allied Fruits. By Prof. H. Clark Powell. (South African Agricultural Series, Vol. 8.) Pp. 355 + 83 plates. (Johannesburg: Central News Agency, Ltd., 1930.) 21*s.* net.

In 1913 the exports of citrus fruit from South Africa amounted to 70,000 cases; by 1929 this had risen to 1,200,000. At the present time only 22 per cent of the citrus trees in the Union of South Africa are more than eight years old. Citrus groves are established from the Zoutpansberg, in the north of the Transvaal, to Uitenhage, in the extreme south, and Clan William, in the extreme west of the Cape of Good Hope. Such are the very varying climatic and soil conditions under which this young industry is established. There is no well-defined citrus area such as exists in Florida and California. So far as possible, the author has drawn on South African experience, and much information has been collected from the successes and failures of the past. Where South African experience does not exist—and a large amount of research and investigation is shown to be still necessary—the author has of necessity to draw on work done elsewhere.

The book deals in a thoroughly practical manner with all aspects of citrus growing, and should prove a great help to the grower and the industry in general, besides being a valuable addition to citrus literature. A short account is given in the concluding chapters of citrus culture in other parts of the world.

Economics.

Youth and Power: the Diversions of an Economist. By C. R. Fay. Pp. ix + 292. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1931.) 10*s.* 6*d.* net.

In this book Mr. C. R. Fay discourses on a wide range of subjects, including topics so varied as the outlook of youth, trade unions, Adam Smith and foreign trade, unemployment, immigration, and the psychology of revolt. Its scope is thus better indicated by the sub-title, "Diversions of an Economist", rather than by the main title. A special interest is attached to Mr. Fay's reflections, since he has had exceptional opportunities of studying conditions in Great Britain, Canada, and the United States. In discussing unemployment, for example, he is thus able to contrast conditions in various countries. In France there is a great degree of economic stability, due largely to her agricultural democracy, but in Great Britain technological unemployment, which is distinctively American, has been added to various pre-War causes. These, playing upon Britain's peculiar post-War situation, have produced a position in which one industry after another is depressed. The present problem, in his view, is one of readjustment to a new world balance which calls for an unusual degree of co-operation between employers and employed. The book as a whole is very readable and should interest the general reader as well as the professional economist.

Britain and World Trade: Quo Vadimus and other Economic Essays. By A. Loveday. Pp. xxi + 229. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1931.) 10*s.* 6*d.* net.

This volume consists of a series of essays written at various dates and now collected in book form. The subjects discussed are: post-War economic tendencies up to 1925; gold and prices; Britain and world trade; economic progress 1925–29; tariff level indices, and an essay entitled "Quo Vadimus?" in which present-day economic trends are examined. Mr. Loveday is head of the Economic Intelligence Service of the League of Nations Secretariat, Geneva, and is thus well qualified to discuss these problems. He points out that Great Britain's share in world trade has declined and continues to decline. Whereas in 1913 she claimed 13·9 per cent of all exports, in 1928 this had fallen to 11·2 per cent. He considers that the forces determining economic development to-day demand a revision of industrial methods and a modification of industrial technique which have perhaps been less fully accomplished in Great Britain than elsewhere, though mobility of demand and the rapid progress of science render suppleness of industrial mechanism more necessary than ever. The book suffers from the form in which it is composed, and would have been improved if rewritten into a homogeneous whole.

Geography and Travel.

The Groundwork of Modern Geography: an Introduction to the Science of Geography. By Dr. Albert Wilmore. Third edition, revised and enlarged. Pp. xxii + 533 + 27 plates. (London: G. Bell and Sons, Ltd., 1931.) 7*s.* 6*d.*

A book which has now reached its third edition, in addition to five reprints of the earlier editions, requires no technical criticism; it has obviously filled a long-felt want. We have approached it from the point of view of one who from boyhood has wandered about England and later in many other lands, having been taught to use his eyes and understand something of their geography, geology, flora and fauna, etc., and has in turn tried to impart some of this knowledge to the next generation. With such interests one is never alone; indeed, the trouble is to find time to do all the things that tumble over one another in their urgency when in new country. What a treasury of other people's learning and experience is disclosed by Dr. Wilmore; his simple classifications, the succession of chapters on land forms, make all so clear; so that one can without great difficulty puzzle out some of the riddles of our own Lake District, not unassociated in our memories with the genial enthusiasm of Dr. Marr, and even attempt the more complex conundrums set us in the High Alps.

Climate on holiday means fine weather, yet we are able to realise the need for rain and appreciate Charles Kingsley's reasons for declining to pray for the rain to cease. The book should be better known; it can add enjoyment to every holiday spent in the hills, whether we go to the Alps in summer or to the English Lakes at wet Eastertide, and it need scarcely be said that it should form one of the few books included in the restricted luggage for a cruise, that is, if the voyager wishes to behold with seeing eyes.

The fine illustrations are not the least attractive part of the work. E. F. A.

Der Kilimandjaro: sein Land und seine Menschen. Von Dr. Walter Geilinger. Pp. 182 + 95 Tafeln. (Bern und Berlin: Hans Huber, 1931.) 15 francs; 12 gold marks.

The author, a doctor in Zurich, visited East Africa in 1928–29 and ascended Kilima Njaro, the highest of African mountains. His book contains a short, interesting account of the country and its people, and conveys a pleasing impression of the author's ecstatic enjoyment of the beauties and wonders seen during his tour. He combines his own observations with information from general literature, in the list of which British authorities occupy a fair share. Special features are dealt with in a series of useful appendices, including those on the flora, topography, and geological history of Kilima Njaro. The author's main interest was in the flora and forest trees and the contribution of the vegetation to the scenery of the district.

The text is general and popular, and gives a good picture of the present conditions of the country. The most valuable feature of the book is its illustrations, including 156 photographs and 4 coloured plates. Most of the photographs are by the author and are of the trees, more conspicuous plants. the natives, the glaciers and ice formations on Kilima Njaro, the giraffes, antelopes, and other big game. The illustrations form a graphic and useful record of the natural history of the mountain and its surrounding plains. The name of the mountain is spelt Kilimandjaro on the title page and in the text and Kilima Njaro on the cover. The one drawback of the book is the absence of an index, which would have been especially useful in regard to the flora.

Alarms and Excursions in Arabia. By Bertram Thomas. Pp. 296 + 24 plates. (London: George Allen and Unwin, Ltd., 1931.) 15*s.* net.

The geographical area covered by Mr. Thomas's book is wider than the title indicates. Of the 'adventures' which he records—and no other name would describe them so exactly—two out of the five have Mesopotamia as their setting and the three others southern Arabia, after he had been appointed Vizier of the Sultan of Oman and Muscat. Although the interest of the first two is essentially that of a record of a difficult military and political situation, Mr. Thomas's insight into the character of the tribal Arab gives it an added value for those who appreciate the significance of racial characteristics in their bearing on the task we have undertaken in Mesopotamia. Of his work and travels in Arabia the scientific results have already been published in the *Geographical Journal* and elsewhere. Here Mr. Thomas gives his readers the lighter side—fighting and politics — and here and there intriguing thumb-nail sketches of customs and beliefs. His book throws an interesting sidelight on the conditions in which his valuable additions to our geographical and ethnological knowledge of Arabia have been made. The recent award of the Burton Memorial Medal of the Royal Asiatic Society to the author is a fitting and well-deserved recognition of his work in the Great Sandy Desert.

Geology.

Central Asiatic Expeditions. The Permian of Mongolia: a Report on the Permian Fauna of the Jisu Honguer Limestone of Mongolia and its relations to the Permian of other parts of the World. By Prof. Amadeus W. Grabau. With a Chapter on the Relations of the Jisu Honguer Formation to the General Geology of Mongolia, by Dr. Charles P. Berkey and Frederick K. Morris. (Natural History of Central Asia, Vol. 4.) Pp. xliii + 665 + 35 plates. (New York and London: G. P. Putnam's Sons, 1931.) 42*s.* net.

With the exception of a chapter on the general geology of Mongolia by C. P. Berkey and F. K. Morris, this work is devoted to a detailed account of the fauna of the Jisu Honguer limestone of southern Mongolia, with a discussion of its age and relationship to similar faunas of other regions, more particularly to Russia and India. Brachiopods are the predominating group in the fauna; of these, no less than 99 species and varieties are recognised, belonging principally to the spiriferids, the productids, and the streptorhynchids, with the remarkable form *Richthofenia.* The Mollusca are relatively few in number, there being only 19 species and varieties of gasteropods and 17 of lamellibranchs. Noteworthy features are the rarity of corals and Polyzoa and the absence of Foraminifera, echinoderms, trilobites, and cephalopods. To account for this limitation of the fauna, combined with signs of dwarfing shown by many of the brachiopods, the author suggests that the salinity of the water was below normal, and compares the conditions with those now existing in Pechili Bay, a nearly enclosed area freshened by the waters of the Yellow River, where some groups of organisms usually abundant in the open sea are rare or wholly wanting.

The Jisu Honguer is correlated with the Uralian of Russia and the Productus Limestone of India. By most geologists the Uralian is regarded as of Upper Carboniferous age, but Prof. Grabau gives reasons for assigning it to the Lower Permian.

Lehrbuch der Geologie. Teil 3: *Geologische Landerkunde.* (*Regionale Geologie.*) Von Prof. Dr. F. X. Schaffer. Lieferung 1. Pp. vii + 96. (Leipzig und Wien: Franz Deuticke, 1930.) 6 gold marks.

The third volume of the "Textbook of Geology", by Prof. Schaffer, Director of the Geological and Palæontological Department of the Vienna Museum, is devoted to regional geology. The first part includes the general introduction, illustrated by a map of the world showing the author's conclusions as to the distribution and character of the main earth-forms. He divides them into three main groups; the Epeirogens are the continental areas; the Orogens are the mountain bands, in which he includes all the North Atlantic, the western part of the Southern Ocean, and the south-western part of the Pacific. His third group includes the Pelagogens, or the areas of the Pacific, South Atlantic, and Indian Ocean which he regards as having been permanent. All the eastern Pacific, he considers, has been an ocean since the pre-Cambrian, and he supports this view by the opinion of Holdhaus that the insect faunas of the Polynesian islands are oceanic—a conclusion rejected by other authorities on the entomology of that region.

Most of the present part is occupied by summaries of the geology of the Pacific Ocean and its islands, of the Australonesian Orogen, based largely on Stanley's works on New Guinea, and by accounts of New Zealand, Australia, and the Antarctic continent and islands. The chapter on India is begun. The author has visited Australia, and his chapter on the Australian region shows general recognition of the predominant influence of block-faulting and of the Great Valley of South Australia as a rift valley. Prof. Schaffer briefly considers the artesian basin of east-central Australia and accepts the view that the wells are discharging an accumulation of fossil water or of magmatic water, and he remarks that many of the wells have already shown a great decline in productivity. In the account of New Zealand he tabulates the classifications of Park, Marshall, and Morgan.

Chemistry.

A Comprehensive Treatise on Inorganic and Theoretical Chemistry. By Dr. J. W. Mellor. Vol. 11: *Te, Cr, Mo, W.* Pp. xii + 909. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1931.) 63*s.* net.

THE eleventh volume of Dr. Mellor's "Comprehensive Treatise" includes the element tellurium, held over from the previous volume on sulphur and selenium, and the half-brothers of the oxygen family, chromium, molybdenum, and tungsten, but without uranium. All these elements raise interesting problems of valency; but the section on the valency of tellurium is unfortunately already out of date, since the evidence cited on p. 32 for the coplanar configuration of the four radicals in the telluronium salts has been obsolete since the end of 1928, whilst positive evidence of the tetrahedral configuration was provided at the end of 1929. The chromium ammines are catalogued with characteristic thoroughness under ninety subheadings, and stereo-isomerism is suggested as a possible explanation of the existence of multiple forms of certain members of the series, but the index contains no references by which general phenomena, such as co-ordination, isomerism, or stereo-isomerism, can be discovered. On the other hand, the interesting oxy-salts, which are so characteristic of this family of elements, can be traced quite readily by referring to entries under chromyl, molybdenyl, and uranyl compounds.

As his task approaches completion, however, it becomes increasingly clear that Dr. Mellor's principal achievement is to provide a monumental index to the literature of inorganic chemistry during the preparative period of its development, and thus to ensure that nothing of importance is lost or permanently forgotten. This programme calls for page after page of closely packed references and a highly condensed text, with the result that the more modern problems of valency and chemical properties in their relation to the electronic structure of atoms and molecules must necessarily play only a subsidiary part in the scheme. The treatise is therefore, in the main, a record of detailed facts accumulated during a century of arduous work, and the author is to be congratulated on the inclusion of so many recently acquired details, for example, of crystal structure, rather than to be criticised for the fact that these are scattered at such distant intervals amongst the results of earlier work.

Fundamentals of Organic Chemistry. By Prof. Harry F. Lewis. (International Chemical Series.) Pp. viii + 390. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1930.) 13*s.* 9*d.* net.

IN the preface to this book, the author directs attention to the lack of a recent American textbook of organic chemistry based on what he calls the "Atomic Linking Theory". This somewhat misleading expression is intended to denote a theory based upon the Lewis-Langmuir conception of electronic linkages rather than upon the mere spatial orientation of the molecules as developed from the work of Kekulé, van 't Hoff, and others. But the author soon encounters difficulties, and on page 10 he confesses that "the arrangement of electrons in ethylene and acetylene is not well understood". He is therefore obliged to fall back upon a study of old-fashioned linkages and groupings, and abandons the idea of discussing electronic linkages. Very little stress is laid, however, upon the use of three-dimensional formulæ and the description of optical activity is rather inaccurate. Thus the expression "straight chains of carbon atoms" is used, and an optically active compound is described as one "having the property of bending the plane of polarised light". The chapter on the characteristics and analysis of compounds is a mere outline and would be more useful if it were illustrated with diagrams.

Nevertheless, the book has some good features. Thus, in many of the problems set, reference to original papers is necessary in order to obtain numerical data, which are to be used in plotting graphs, and the student acquires the habit at an early stage of consulting the original records. Emphasis is also laid upon technical developments of recent date, for example, new fermentation processes, new methods of cracking hydrocarbons, the catalytic oxidation of naphthalene, and technical applications of Friedel and Crafft's reaction. Many illustrations of plant are given.

Quantitative Pharmaceutical Chemistry: containing Theory and Practice of Quantitative Analysis applied to Pharmacy. By Prof. Glenn L. Jenkins and Prof. Andrew G. DuMez. (McGraw-Hill Publications in Pharmacy.) Pp. xxiii + 408. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1931.) 17*s.* 6*d.* net.

This book bases a four years' course of quantitative analysis for students of pharmacy on the various methods of assay described in the United States Pharmacopœia and National Formulary. It may be questioned whether such a course, even for pharmaceutical students, will give the groundwork which is desirable, seeing that the methods are intended only for standardised articles of a high degree of purity. So far as it goes, however, the course is judiciously arranged; the typical processes are, in general, adequately explained and questions and problems are set at the conclusion of the exercises. The details of some of the processes should have been criticised for the edification of the student, who may be left with the impression that it is usual, in the electrolytic assay of mercury, to employ a cathode weighing 700-800 gm. when the expected increase in weight is about 0·3 gm., or that in the determination of nitrogen by the Kjeldahl process there is no likelihood of loss of ammonia by the addition of strong soda solution to the diluted acid solution in an open flask.

The book is well printed and is remarkably free from typographical errors. A few loose statements are apparent; for example, it is explained that a 0·2 per cent solution of sodium chloride just acidified to litmus paper with nitric acid must not be heated since chlorine may be lost thus: $6HCl + 2HNO_3 \rightarrow 3Cl_2 + 4H_2O + 2NO$. A more serious error is that the student is directed to determine colorimetrically the *p*H of alcoholic solutions. The technique of repeated ether extractions should have included the more usual and convenient practice of blowing off the ether layers instead of running off the aqueous layer. J. R. Nicholls.

Chemical Composition: an Account of the Methods by which Atomic Weights and Molecular Formulæ have been Determined. By Dr. A. K. Goard. Pp. viii + 304. (London: Sidgwick and Jackson, Ltd., 1931.) 5*s.*

Twenty-seven years ago, Miss Ida Freund wrote a book on " The Study of Chemical Composition " which at once acquired a permanent value by reason of the fact that it was made up very largely of appropriately selected quotations from original sources. Miss Freund's book (which has long been out of print) was, however, too expensive to be used extensively by students, and was mainly a source of information and inspiration for those who were responsible for the teaching of chemistry in schools or universities.

It appears certain that Dr. Goard must have been amongst their number, since he has set himself the task of handing on, in a more elementary form and at a much lower price, the doctrines which formed the subject of the larger work. He has carried out his task in a way which appears to be entirely satisfactory, since the shortness of many of his chapters must be very encouraging to his readers; but for a real test of success it would be necessary to discover what impression the book has made on the author's own classes at Marlborough, or on other juvenile readers who have been introduced by it to a section of chemical theory which can be made very dull, but can also form the subject of a rather fascinating story.

The reviewer is too hardened a chemist to make this test in his own person, but would commend the book to those who are in a position to use it for this purpose, since he is certain that nothing but good can come from closer contact between the beginner of to-day and the scientific pioneers of yesterday.

Lehrbuch der physikalischen Chemie. Von Prof. Dr. Karl Jellinek. Fünf Bände. Lieferung 10 (Band 4): *Die Lehre von der Statik chemischer Reaktionen (Schlussteil) und die Lehre von der chemischen Kinetik.* Erste und zweite Auflage. Pp. 288. (Stuttgart: Ferdinand Enke, 1931.) 26 gold marks.

Prof. Jellinek's detailed treatise provides the worker in physical chemistry with a survey of the theory and experimental investigations which is at the same time exhaustive and comprehensible. Great care is taken not to pass over points of difficulty, and all the equations used are deduced in full, numerical applications in most cases making their significance perfectly clear. Unlike some treatises, it takes full account of work done in Great Britain and the United States, so that it is international in character. The references to the literature are very complete, and it is clear that the author has made extensive use of original papers.

The present volume extends the treatment of liquid solutions begun in the preceding one, and deals with equilibria in weak electrolytes. The activity function is used throughout, and since such matters as neutralisation curves, buffer solutions, and indicators are included, the volume contains much of interest to biochemists as well as to investigators in pure physical chemistry and technical workers. The text is very clearly printed, and numerous curves and diagrams are included.

The book may be strongly recommended as forming a part of what is undoubtedly the most important and authoritative treatise on physical chemistry of the time. Although the detailed treatment makes it suitable for the specialist, the careful explanations given of all the theories are such as could usefully be read by students able to understand German.

Solvents. By Dr. Thos. H. Durrans. (Monographs on Applied Chemistry, Vol. 4.) Second and revised edition. Pp. xv + 180. (London: Chapman and Hall, Ltd., 1931.) 10*s.* 6*d.* net.

The term ' organic solvent ' has acquired an altogether new meaning during the past year or so in connexion with the various sections of the plastic industry, particularly cellulose lacquer and artificial silk. The older solvents like acetone have been manufactured by new methods in much greater quantities and at much lower prices; newer solvents are being made and applied to industry all the time, so that, as is often said, what were last year's laboratory curiosities are this year sold in tank waggons. Progress in the new field on the manufacturing side has been largely due to the use of processes involving catalysts, which have led to new syntheses from simple raw materials such as alcohol.

The fact that a new edition of this book has been called for within a year is a proof both of the interest taken in the subject and of the clarity and utility of the work. The method again adopted is to deal with the fundamentals in the first section of fifty pages and to devote Part 2 to the individual solvents in considerable detail. The chapter on plasticising solvents has been considerably extended and now contains notes on forty-one substances suggested for this purpose.

The book is readable, commendably crisp, and will be of value to all who use such solvents.

E. F. A.

Practical Physical Chemistry. By Prof. Alexander Findlay. Fifth edition, revised and enlarged. Pp. xii + 312. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1931.) 7*s.* 6*d.* net.

The fifth edition of Prof. Findlay's "Practical Physical Chemistry" may be regarded as celebrating the half-jubilee of the book, which was first issued in 1906. Throughout this period its general character has been maintained, but its usefulness has been increased by the introduction of new experiments from time to time. In the present edition the preface tells us that these new experiments deal with gaseous dissociation, vapour pressure of liquids, viscosity of highly viscous liquids, potentiometric methods, and the use of indicators for the determination of hydrogen ion concentration, whilst attention has been directed to the concept of the activity of strong electrolytes and to the phenomenon of salt effect. The vapour pressure of salt hydrates and the freezing points of binary mixtures have also received brief treatment.

The new edition does not call for any further comment, except for a word of congratulation to the author on his success in inhibiting the physicochemical phenomenon of 'ageing' from which books on chemistry are liable to suffer severely.

Die Glykoside: Chemische Monographie der Pflanzenglykoside. Von Dr. J. J. L. van Rijn. Zweite ergänzte und neubearbeitete Auflage von Prof. Dr. Hugo Dieterle. Pp. viii + 620. (Berlin: Gebrüder Borntraeger, 1931.) 48 gold marks.

The first edition of Dr. van Rijn's book was published so long ago as 1900; it has now been revised and rewritten by Dr. Dieterle.

The chemistry of the individual glycosides which have been found in plants is described in the order of plant families, a method of arrangement which in our opinion, as indeed the author confesses, leaves much to be desired, as it makes the book merely a catalogue of individual substances and does not bring out any general group relationship among the glycosides or assist the reader to study their significance. For each substance the method of preparation, the physical properties, and the constitution of the non-sugar section or aglucone is indicated; a reference is also made to the physiological activity. The work is costly, and suitable for reference in the library rather than for the inspiration of the research worker. E. F. A.

Physics.

Lectures on Theoretical Physics delivered at the University of Leiden. By H. A. Lorentz. Authorised translation by Dr. L. Silberstein and A. P. H. Trivelli. Vol. 3: *Maxwell's Theory,* edited by Dr. H. Bremekamp; *The Principle of Relativity for Uniform Translations,* edited by Dr. A. D. Fokker. Pp. xi + 326. (London: Macmillan and Co., Ltd., 1931.) 21*s.* net.

This, the last, volume of Lorentz's "Lectures on Theoretical Physics" contains a translation of two courses, namely, "Maxwell's Theory", edited in the Dutch by H. Bremekamp and published in Leyden in 1925, and "The Principle of Relativity for Uniform Translations", edited by A. D. Fokker and published in 1922.

The first section contains chapters on the electromagnetic field, electrostatics, stationary currents, induction currents, and the electromagnetic theory of light. The second section, on the restricted theory of relativity, contains chapters on the principle of relativity, the various transformation formulæ and their interpretation, the mechanics of a particle, the inertia of energy, and electromagnetic phenomena in moving bodies.

Although the work treats of very familiar and almost old-fashioned material, it treats them in a manner which is both stimulating and refreshing, the simplicity and generality of the style being reminiscent of Lorentz at his best. The various topics are dealt with in sufficient detail to bring out all the underlying physical principles and their bearing on the mathematical formulations, and they are woven together so as to form a complete and comprehensive text on the subject.

As with the first two volumes, the translators have not always been too happy in their choice of words and phrases, but on the whole the book is a worthy companion to its predecessors, and does honour to the great master whose thoughts it expounds. It can be strongly commended to all who are interested in the subjects with which it deals and, in particular, to students and teachers in need of an introductory textbook to this side of modern physics. G. H. L.

Magnetism and Electricity. By E. Nightingale. Pp. xvi + 294. (London: G. Bell and Sons, Ltd., 1931.) 4*s.* 6*d.*

The high standard set in the author's "Heat, Light, and Sound" is fully maintained in the present work, which covers roughly the school certificate or matriculation range. For students following a school course it would be difficult to imagine a more efficient or attractive presentation of a subject which, thanks largely to the universal interest in wireless, may be regarded as the most popular branch of science, but is often handicapped by heavy or unimaginative treatment. The historical development is prominent throughout. This, as is nowadays generally realised, adds greatly to the reality and interest of science. Here, moreover, instead of the great pioneers being left as little more than names, they are made to 'live' by judicious sketches of their life and times, with portraits, numerous extracts from their original papers, and reproductions of their diagrams and apparatus. The lesser known experimenters receive due recognition, in which connexion Bennett's work and original illustrations are notable. Equally with the historical aspect a practical line of study is followed, aided by a wealth of simple diagrams and numerous ingenious and up-to-date modifications or improvements of the usual experiments. Practical applications to everyday life are emphasised.

The quantitative side has been made to appear integral with theory. Each chapter is provided with a summary, simple questions, and an ample number of questions grouped together, drawn from papers of the various school certificate authorities; worked numerical examples are added. A concluding chapter deals briefly with modern ideas and advances, such as conduction through gases, wireless, and photoelectricity. The book is altogether admirable—a maximum is accomplished in a minimum of space. N. M. BLIGH.

Electricity for Everybody: Handbook for 1931; an Electrical Compendium incorporating a Gazetteer of Electricity Supplies, a Directory of Electrical Contractors, and a Diary from April 1931 to March 1932. By R. Borlase Matthews. Pp. lxxxvii + 470. (London: Electrical Press, Ltd., 1931.) 5*s.* net.

Now that electricity supply is available to many, a demand has arisen for accurate knowledge about the various uses to which this supply can be applied for domestic and factory purposes. This book will be useful in this connexion. It contains a useful diary, a calendar, and a section dealing with general principles which can be readily understood by anyone with a little technical knowledge. There is a section dealing with electric lighting, heating, cooking, and power in the home, due stress being laid on the economic and æsthetic factors. The costs of electricity in public and private buildings and in factories are discussed, and simple methods of computing them are given.

Mr. Borlase Matthews is a specialist in the many uses to which electricity can be put on a farm or in a garden. It is used to increase the comfort and hence the utility of live-stock. It also increases their productivity. The heating and lighting of apiaries increases the productivity of each hive by from 15 lb. to 17 lb. of honey per annum. Electric heating of greenhouses for forcing is very readily done, and an even temperature is easily obtained by a thermostatic control. The soil heating of frames and hot beds by means of electric cables is extending in Great Britain. It is much better than using the variable heat given out by manure.

Post-Primary Science. By W. F. F. Shearcroft. Book 1: First Year's Course. Pp. 194. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1930.) 2*s.* 6*d.*

THIS is the first of three books designed to cover the first three years of a five-year course, leaving two years for a more specialised study. The object is to overcome the difficulty, so painfully obvious to every teacher, that science tends to be studied in water-tight compartments, and progress in one branch is hindered by ignorance of another, ending generally in a knowledge of a little heat and a little chemistry.

Here science is generalised in the extreme by a treatment of measurements, heat, light, sound, and magnetism and electricity, with a trace of mechanics, all merging into each other. The presentation is in the simplest possible style, and in a manner likely to interest pupils from the age of eleven years, for whom the book is intended. The scientific method is the keynote throughout, and the course, being primarily experimental, should certainly train the pupil to think. The provision of a table of contents would be an advantage, an index not being a satisfactory alternative. N. M. BLIGH.

An Introduction to Quantum Theory. By Dr. G. Temple. Pp. 196. (London: Williams and Norgate, Ltd., 1931.) 12*s.* 6*d.* net.

THIS book is concerned more with the ideas upon which quantum mechanics is based than with the applications of the theory to physical problems. The book opens with a general discussion of the principle of duality between waves and particles, followed by a chapter on the theory of photons, in which the idea of a wave function for a single light quantum is introduced. A wave theory of matter is then developed along unusual lines. Electric charge is treated as a fluid which obeys hydro-dynamical laws, and by means of certain special assumptions its behaviour is shown to be governed by a wave equation equivalent to that of Schrödinger. Thus, without interpreting any of the symbols in terms of probability, a considerable number of the results of wave mechanics can be deduced, including the energy levels of a hydrogen atom and the splitting in a magnetic field. The treatment is complicated and involves a considerable amount of mathematics, and therefore can scarcely be recommended to a beginner.

The author then shows that it is necessary to introduce the idea of probability in dealing with collision problems, and in dynamical problems involving the interaction of two or more particles. There follow chapters on quantum algebra and matrix mechanics, attention being concentrated on the formal side of the theory, and very few examples being given. As would be expected from the author's own researches, there are interesting chapters on the relativity wave equation and on the spinning electron.

Quartz Resonators and Oscillators. By P. Vigoureux. Pp. 217 + 13 plates. (London: H.M. Stationery Office, 1931.) 7*s.* 6*d.* net.

WRITTEN round the practical use of quartz in vibrating systems, this monograph will be of interest to many classes of readers. It describes the preparation of suitable pieces of crystal from the natural material—apparently by no means a difficult operation—the connexions and mathematical theory of circuits involving these, and the physics of quartz. We should like to direct special attention to the illustrations, and particularly to the photographs of the electrical discharges which vibrating crystals can set up in a partial vacuum, and of the interference fringes seen with a crystal oscillator close to optical flat. It would be difficult to devise more beautiful demonstrations of the modes of vibration of rods and plates. Including as it does an extensive bibliography, the book serves a useful purpose in co-ordinating existing results, and can scarcely fail to stimulate further research. K. G. E.

Engineering.

(1) *Cross-Country Flying.* By Major Oliver Stewart. Pp. ix + 116 (12 plates). (London: Constable and Co., Ltd., 1931.) 6*s.* net.

(2) *Flying as a Career: a Popular Guide for all proposing to obtain a Position in the new Industry as a Pilot, Navigator, or Aircraftsman.* By Major Oliver Stewart. Pp. ix + 81 + 12 plates. (London: Sir Isaac Pitman and Sons, Ltd., 1931.) 3*s.* 6*d.* net.

(1) MAJOR STEWART is a writer of the kind that seems to be prevalent in aviation, to its great advantage. He has the ability to explain the most abstruse problem to the non-scientific reader by selecting the essentials, and presenting them simply yet accurately. His book, " Cross-Country Flying ", deals with the use of the compass, air speed indicator, turn and drift indicator, bubble inclinometer, etc., in the air, and the general use of maps, course plotters, and calculators on the ground. He avoids the complicated mathematical theory upon which much of it is based, without descending to such a simplicity as to offend the intelligence of the reader.

There are chapters on the regulations laid down by law to be observed when flying, and a sufficient explanation of meteorology and instructions for the use of wireless communication to enable the pilot to make use of the broadcast services in this respect. A chapter on bad weather flying is unfortunately only too appropriate in Great Britain at the present time.

(2) " Flying as a Career " deals in a strictly impartial manner with the various possibilities in aviation to-day. The author is quite rightly severe in his condemnation of the Royal Air Force ' Medium Service ' system as a ' blind alley ' occupation. Aspiring aviators and their parents can read this book with considerable advantage.

The Light Aeroplane Manual. By F. D. Bradbrooke. Pp. ix + 251. (London: Chapman and Hall, Ltd., 1931.) 10*s.* 6*d.* net.

THIS is an exceedingly well written book but with an entirely misleading title. The term ' Manual ' suggests the practical outlook, and detailed descriptions of light aeroplanes and their engines, together with hints on their use and maintenance, are expected. Actually the book is a simple and remarkably correctly written treatise on the theory of flight, both from the point of view of why an aeroplane flies and, appreciating this, how to fly it properly. The author has skilfully avoided the all too common pitfall of making a statement scientifically incorrect in order to simplify it. He has not dealt with the more complex mathematical and physical outlook, but as the book is obviously intended for the user rather than the producer of an aeroplane, his action is justified.

The chapter headed " Types of Aircraft " is rather a disappointment, in that it is merely a description of some present-day aeroplanes, which will serve to make the book out of date rapidly, remembering the rate at which aircraft design is progressing to-day. A more general discussion upon the broad classification of types, into which modern aircraft is automatically dividing itself, would have been more in keeping with the rest.

The book should certainly be read by all aircraft owners who are ambitious to be something more than mere aerial chauffeurs, and should be useful to elementary students of aeronautics.

The Mechanical Properties of Wood: including a Discussion of the Factors affecting the Mechanical Properties, Working Stresses for Structural Timber, and Methods of Timber Testing. By Prof. George A. Garratt. Pp. ix + 276. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 17*s.* 6*d.* net.

THIS American publication deals with a subject that is receiving more and more attention from forest utilisation officers, wood technologists, architects, and manufacturers, for all find that it is very necessary that reliable information should be available upon the mechanical properties, not only of a few woods, but also of all the important commercial timbers. Moreover, it is necessary that there should be an international understanding about any research that is being carried out.

The book under notice, whilst primarily a textbook for students, will also be found of value to other people interested in timber and its manufacture. The author has divided his work into four parts. Part 1 treats of the relation of wood to stresses and strains, which are included under the three general headings tensile, compressive, and shearing, each of which is then dealt with separately and subdivided as necessary. Illustrations and tables add materially to the interest of the descriptions. Part 2 deals with factors affecting the mechanical properties of wood, such as knots, checks, shakes, cross grain, decay, etc. Preservative treatment is given full consideration, time of felling and its effect on timber, and various other pertinent matters.

Part 3 deals with working stresses for structural timbers. This part will be found of great use to architects and engineers, for it goes very carefully into the question of working stresses for joists, planks, beams, stringers, round posts, wooden columns, etc., with tables showing the comparative strengths of various American timbers. Part 4 treats of timber testing, forms of material tested, size of specimens in relation to tests, moisture determination, machine for static tests, speed of testing machine, with numerous descriptions of tests. At the end of each part is a list of references to questions dealt with in the respective part. The work has a good index.

Charts and Data on Marine Boiler Design: a Summary of the Standard Formulæ in Chart Form with Tables and Notes. By H. C. Walker. Pp. xii + 55. (London: Chapman and Hall, Ltd., 1931.) 25*s*. net.

Though to-day in all naval vessels, and in a considerable number of mercantile vessels, water-tube boilers are used, the standard form of boiler for ships, both small and large, has been that with a cylindrical shell and internal cylindrical furnaces, from which the gases pass into vertical combustion chambers and through nests of tubes. Such boilers are sometimes referred to as return-tube boilers, as the smoke returns to smoke-boxes fitted at the same end as the furnace mouths; but to all marine engineers they are just known as marine boilers. The design of this type of boiler involves the consideration of the strength of cylinders, of flat plates, of corrugated furnaces, and of riveted joints; and the dimensions of the various parts are governed by rules laid down in an official document, "Standard Conditions for the Design and Construction of Marine Boilers", published by H.M. Stationery Office. From the formulæ given in these rules the calculations are made. To obviate the necessity for these calculations, Mr. Walker has prepared a series of 17 charts and 25 tables, from which, once his methods are grasped, readings are the work of a few moments only, and the possibilities of error are practically eliminated. The size of the volume, 13 in. × 10 in., has enabled the charts to be of a sufficiently large scale; they are printed on stout paper, and have been rendered easy for reference. The author has thus provided a reference book which should be of much use for all concerned with the design of marine boilers.

Machine Drawing and Design: a Textbook of Intermediate Standard for Engineering Students. By W. Abbott. Pp. 208. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1930.) 7*s*. 6*d*. net.

This volume is divided into two parts. Part 1 contains the more important details of machinery, such as fastenings, shafts and fittings, bearings, gearing, valves, parts of engines and turbines, with simple explanations of the principles of design. It is assumed that the subjects of mechanics and the strength of materials are being studied conjointly. Part 2 is devoted entirely to exercises, and includes some examples taken from university and Whitworth scholarship examination papers. Most of the drawings are presented in pictorial form, thus preventing the mere copying of orthographic projections and enabling the appearance of the object to be readily understood. The designs included are representative of good modern practice.

There is evidence throughout the volume that the author has taken pains to produce an excellent and well-graded course suited to the requirements of intermediate students. Those interested in the teaching of engineering who are acquainted with Mr. Abbott's former work on "Practical Geometry and Engineering Graphics" will welcome the present useful and practical addition to the literature of engineering drawing.

Civil Engineering Design. By Arthur A. Fordham. Pp. xi + 212 (45 plates). (London: Chapman and Hall, Ltd., 1931.) 21*s*. net.

This book is intended to be of service in the drawing office to students taking courses in civil engineering who have acquired a knowledge of strength of materials, theory of structures, etc. The volume contains twelve designs completely worked out with the necessary calculations and drawings. These include a steel frame building with grillage foundations, steel dock gates, two steel roof principals, one of which is a two-hinged braced arch, five bridge designs, including both steel and reinforced concrete, a masonry dam and an earthen dam. These designs have been carefully worked out and will be useful to the student in showing how principles are applied in practice; also by modifying specified dimensions the illustrated designs may be used as models for his own designs.

There are not too many volumes on this subject published in Great Britain; most of the great mass of material at our disposal is scattered in periodicals and transactions of engineering institutions. The present volume will therefore be appreciated by many busy teachers who have to provide data for students' designs. It is unfortunate that the size of the book—12½ inches by 10 inches—required to present the drawings properly, and its weight, which is about 4 lb., make it clumsy to handle and lead to a good deal of wasted space in the text. In view of the excellence of the matter, however, this must be regarded as a minor blemish.

Mathematics.

Numerical Mathematical Analysis. By Prof. James B. Scarborough. Pp. xv + 416. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1930.) 25*s*. net.

Most of the ground of Prof. Scarborough's book on numerical analysis is covered adequately for English readers by Whittaker and Robinson's "Calculus of Observations", and the new work interests us chiefly for its revelation of differences between the American material and our own.

The best feature of the book is the attempt wherever possible to frame estimates of reliability. In one case the author is led to an important conclusion, for he finds that in spite of its complication Simpson's three-eighths rule carries an inherent error more than twice as large as his one-third rule ; the comparison is between the actual errors that must occur in individual cases, not between upper limits to these errors in general, and it follows that the more elaborate rule has nothing whatever to recommend it.

Like the account of quadrature, the account of the numerical integration of differential equations is thorough ; four distinct methods are compared and illustrated, and the author's commentary is helpful. But the treatment of other topics is scantier. What are we to say, for example, when the last word on interpolation is with Stirling and Bessel and there is no mention of Everett ? There is an adequate chapter on the root-squaring method of solving an algebraic equation. For simultaneous equations, since the labour involved in the computation of a numerical determinant is not exposed, the tediousness of the Newton-Raphson process is not made evident, and while the iterative process is explained for sets of equations to which it is obviously applicable, nothing is said of the way in which sets of functional equations in general can be prepared for iterative solution. Although probability and statistics are outside the range of the volume, a discussion of normal and probable errors and of estimates of precision is included, to lead up to a chapter on the construction of empirical formulæ which is one of the most important in the book.

The explanations throughout are clear. The author attracts confidence by the honesty with which he applies the standard methods, sometimes to unfavourable cases, and teaches the computer to learn by experience. E. H. N.

(1) *Les méthodes de solution approchée des problèmes de la physique mathématique.* Par Nicolas Kryloff. (*Mémorial des sciences mathématiques*, Fascicule 49.) Pp. 69. (Paris : Gauthier-Villars et Cie, 1931.) 15 francs.

(2) *Angenäherte und symbolische Lösung der Differentialgleichungen der mathematischen Physik und Technik.* Von Prof. Dr. N. M. Kryloff. Pp. 162. (Kharkov and Kiev : State Technical Publishers, 1931.) 3 Kps.

(1) One of the most valuable methods for the approximate solution of the differential equations of mathematical physics is that due to Lord Rayleigh and W. Ritz. This starts by applying the calculus of variations to a certain quadratic form and finally obtains a solution in terms of a convergent series of functions ; a limited number of terms of this series gives an approximation to the exact solution. However, the method as left by its authors was not fully developed, and a great deal of work has been done by Prof. Kryloff, who has written more than thirty papers on the subject. An essential part of his contributions is to show how to estimate the number of terms which must be taken to make the error less than an arbitrary assigned amount. Great variety is possible in the treatment ; in fact, it might be said that each type of equation has its own appropriate method. The account given by Prof. Kryloff in this tract shows that the subject is far from exhausted and offers opportunities for further research.

(2) Another side of the subject is dealt with in the second of the above books of Prof. Kryloff. Unfortunately, this is in the Ukraine language, but there is a summary in German. This book makes considerable advances in the use of the Heaviside operational methods. In particular, it combines them with the methods of approximation on which Prof. Kryloff has worked so long.

H. T. H. P.

Leçons sur la théorie mathématique de la lutte pour la vie. Par Prof. Vito Volterra. Rédigées par Marcel Brelot. (*Cahiers scientifiques*, Fascicule 7.) Pp. vi + 214. (Paris : Gauthier-Villars et Cie, 1931.) 60 francs.

This book deals with one of the newest branches of applied mathematics, namely, the application of differential and integro-differential equations to biological problems of the survival of the fittest, such as the effect of a change in the rate of fishing upon the proportion of the different species of fish, some of which prey upon others.

The first part of the book assumes that the causes have immediate effects. This assumption, though probably far from the truth, has the advantage of allowing a fairly simple and complete mathematical treatment in terms of differential equations. Three fundamental laws are deduced, those of fluctuations, conservation of means, and perturbation of means, which seem of considerable practical importance. The second part of the book endeavours to extend the results of the first to the case where the causes produce delayed effects.

This work is connected with Prof. Volterra's researches on integro-differential equations and their applications to mechanics. In view of the simplifying hypotheses adopted, the results are not likely to be accepted by biologists until they have been confirmed experimentally, but this work has as yet scarcely begun. H. T. H. P.

Miscellany.

Armadas of the Sky : the Problem of Armaments. By Paul Murphy. Pp 120. (London : The Houghton Publishing Co., 1931.) 5*s*. net.

This is a semi-philosophic discussion upon the possible methods of waging war in the future, bearing in mind the uses made of aircraft in the late War, and endeavouring to visualise their probable development by the time the next war breaks out. The reader is left, as it is suspected the author himself is, somewhat breathless, if not entirely drowned, in the sea of argument and counter-argument. The conclusion that appears to emerge from the welter of facts intermixed with visions is that the use of aircraft plus radio communication will so radically alter methods of war that it is impossible to foresee what will happen. In the absence of this knowledge, it is absurd to prepare for a limited number of possibilities only, and impossible to be ready for every one, because of the magnitude of the task. This is rather hard on the professional fighters, who are apparently preparing for a war to be fought on lines similar to the last one, not so much out of ignorance or lack of vision, as because it is the only concrete thing that they have to work upon.

A long chapter is devoted to a dramatic description of the first twenty-four hours of an imaginary war of the future. The capitals of both of the combatants are immediately crippled by the enemies' air fleets, and we are left with the impression that the continuation of the war is impracticable, because of the destruction of the centres of organisation. This holocaust occurs principally because of the rapidity of the blow, which is made possible, first, by the lack of cumbersome mobilisation of armed forces as in previous wars, and, secondly, by the facilities with which orders can be transmitted by wireless.

The author develops a rather ingenious subdivision of methods of use of gas in aerial warfare, which can either be used for killing, temporarily incapacitating a population, or rendering an area uninhabitable. A good many aircraft designers of to-day would not agree with one of his premises, that civil air transport aeroplanes can be used immediately for war purposes; also, that the airship is inferior to heavier-than-air craft in every respect, both in its war and peace applications.

Equality. (Halley Stewart Lectures, 1929.) By R. H. Tawney. Pp. 303. (London: George Allen and Unwin, Ltd., 1931.) 7*s.* 6*d.* net.

"The lever which lifted political and religious boulders will snap when used to move economic mountains" expresses a pessimistic outlook which does not appear to be shared by Prof. Tawney. Nor does he believe that our present social and economic maladjustments are the inevitable results of original sin. "It is more contemptible to be intimidated by distrust of human nature than to be duped by believing in it." His book is an interesting examination of political and economic equality as an ideal, and involves an analysis of the causes, social and psychological, which have resulted in our present degree of inequality. The chapter on "Equality and Culture" is a good tract for the times, and reiterates the useful truth that, if the Kingdom of Heaven is not eating and drinking, "neither is civilisation the multiplication of motor-cars and cinemas, and of any other of the innumerable devices by which men accumulate means of ever-increasing intricacy to the attainment of ends which are not worth attaining".

Critique of Physics. By L. L. Whyte. Pp. xi + 196. (London: Kegan Paul and Co., Ltd., 1931.) 10*s.* 6*d.* net.

The main purpose of this inspiring book is to propose a new structural method of physics where relativity and the quantum theory are shown as special cases of a more general limitation on the classical frame. The proposed method, which the author calls 'unitary theory', is a deductive theory of measurement and of the relations holding between measured quantities, based on a theory of the structure of rods and clocks, in which all theoretically significant lengths, times, or masses appear as functions of one primary length, time, or mass.

It can be gathered, therefore, that the author's method does not arise out of experimental necessities, but is shaped merely on logical postulates based on a searching analysis of the assumptions of modern physics. Without adequate mathematical and experimental developments, it would be difficult to pass a final judgment on the author's endeavour. But he is himself aware of the provisional character of his suggestions, and likes to call his method heuristic rather than scientific. At any rate, if it inspires physicists to look with a constructive suspicion at the postulates of their theories, and try to remedy their obvious logical defects, the labours of the author will not have been in vain.

T. G.

A Defence of Philosophy. By Ralph Barton Perry. Pp. 56. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1931.) 4*s.* 6*d.* net.

Prof. Perry says there is a sort of gentlemen's agreement not to ask ultimate questions. "People do not as a rule insist upon knowing the meaning of things, further than to assign them a place in their world of familiar objects." Yet philosophy differs from other studies in that it continues to press inquiry beyond the point where it customarily stops. "It sets no limits to the questions it asks, save to insist that they shall really be questions." When it is objected that if inquiries are carried too far the methods of science have to be left behind, the philosopher's reply is that he will use what methods he can. Yet the questions which he asks are all familiar in kind: What is real? Why did it happen? How do I know? What ought I to do? Everyone philosophises up to a point; the difference between the metaphysician and the rest of the world is one of degree only, and lies in the thoroughness and obstinacy with which the latter pursues his quest. The philosopher is the intellectual frontiersman, who attempts to domesticate the wild areas which lie beyond the cultivated fields of science. Students of science will read this lecture of Prof. Perry's with interest and with a large measure of agreement.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Determination of the Yard in Terms of the Wave-length of Light.

IN the issue of NATURE for May 9, p. 726, a short account is given of an investigation by Dr. A. E. H. Tutton of the length of the yard in terms of the wave-length of light. This being the first occasion on which the value of the yard in wave-lengths has been directly determined, considerable interest naturally attaches to the result.

In the complete account of his work which has now been published,[1] Dr. Tutton arrives by calculation, from the means of several determinations made in the red line of hydrogen and in the strong yellow line of neon, at a value for the length of the yard in terms of the standard cadmium red line which is in good agreement with that derived from the accepted value of the metre in terms of this line, taken in conjunction with the known ratio of the yard to the metre.[2] Unfortunately, however, he gives no adequate investigation of the probable error of his result, which the internal evidence of his paper clearly shows is very large. In fact, from the nature of the procedure adopted it could not be otherwise.

The method consists in actually counting, to the nearest tenth of a band, the number of interference bands corresponding to three intervals each $\frac{1}{16}$ in. in length—that is, a potential accuracy of the order of 1 part in 50,000—and then stepping up to the yard by a process which, apart from any further errors which may be involved, is one of sheer multiplication. Actually the various individual counts of the separate sixteenths of inches in H_α exhibited differences between themselves amounting to as much as 1·6 bands, with an average difference from the mean in each group of 0·44 band, or nearly 1 part in 10,000. Only two counts were made in Ne_e, the average difference between corresponding pairs being 0·5 band.

As a test on the accuracy of the building-up process, the following comparison is informative. On pp. 312, 316, Dr. Tutton gives the final values he obtained for the length of the yard as—

$$1 \text{ yard} = 1{,}393{,}290{\cdot}5\ \mathrm{H}_\alpha$$
$$1 \text{ yard} = 1{,}562{,}408{\cdot}6\ \mathrm{Ne}_e$$

respectively. From the ratio of these two figures, taking the value of Ne_e as 5852·488 A., the value of H_α can be calculated as

$$\mathrm{H}_\alpha = 6562{\cdot}865 \text{ A.},$$

a result which, though somewhat high, is in tolerable agreement with expectation. The building-up process can, however, add nothing to the accuracy of the original counts, and if we take from pp. 301 and 303 the aggregate mean counts of the three separate $\frac{1}{16}$ in. lengths in the two radiations, we get $16{,}266{\cdot}5\ \mathrm{Ne}_e = 14{,}504{\cdot}3\ \mathrm{H}_\alpha$, from which, using the same value of Ne_e, as above, we find

$$\mathrm{H}_\alpha = 6563{\cdot}536 \text{ A.},$$

showing a difference of 1 part in 10,000 as compared with the result derived from the same data after building up to the yard length.

Incidentally, this more direct calculation gives a value for H_α too far removed from the range of values found for this line by other observers to be acceptable, and it is thus clear that the agreement of Tutton's results with expectation, both as regards the wave-length value of the yard in Ne_e and as regards the derived value of H_α, must be entirely fortuitous, both the original counts and the building-up process being liable to errors of the order of 1 part in 10,000. There are other points in Dr. Tutton's paper which might be criticised, but in these circumstances there is no necessity to enter into details.

At the conclusion of his paper, Dr. Tutton generously records his acknowledgments in respect of certain facilities which I was happy to be able to afford him; and having been to this small extent associated with the work, I the more regret having thus to direct attention to the uncertainty of the results. Had they differed from expectation as much as these remarks show that they easily might have done, the necessity would scarcely have arisen, but their chance agreement with expectation involves a risk that they may be accepted at their face value without sufficient scrutiny. It is very important that the wave-length value of the yard should be determined with all attainable precision. Preparations for such a determination at the National Physical Laboratory are well advanced, and it is expected that the results will become available for publication during the course of next year.

J. E. SEARS, JR.

Standards Department, Board of Trade,
6 Old Palace Yard, Westminster, S.W.1,
Oct. 26.

---

[1] Tutton, *Phil. Trans.*, A, **230**, 293; 1931.

[2] Sears, Johnson and Jolly, *Phil. Trans.*, A, **227**, 281; 1928.

IN rendering due thanks to Mr. Sears, at the conclusion of my paper, for the facilities granted to me for the use of the interferential comparator, which I had the honour to devise and see constructed and installed at the Standards Department of the Board of Trade, in the time of the late Deputy-Warden of the Standards, Major P. A. MacMahon, nothing was further from my intention than to imply any responsibility on the part of Mr. Sears for the results communicated to the Royal Society in my paper. Indeed, he was from the first unsympathetic towards my interferential method. While in Major MacMahon's time the statutory periodic comparisons of the Imperial Standard Yard with its official copies were carried out with my interferential comparator, the interferometric portion was afterwards dismantled, and the instrument used for purely mechanical and microscopic comparisons. Much valuable time had to be spent at the outset of my work in cleaning, refitting, and readjusting the interferometric part, and by the Office of Works electricians in replacing perished electrical fittings, especially those of the thermostat, which maintains the whole comparator room at the official temperature of 62° F. and which had become positively dangerous from disuse. Fortunately, all the base-line work, the actual counting, band by band, of the interference bands (10,846 in yellow neon Ne_e light) in the one-eighth of an inch, was able to be carried out on my own interferometer, an improved copy of that at the Standards Department, in my private laboratory at Cambridge.

The specific criticisms of Mr. Sears are all fully dealt with in the paper. It is unfair to assume an error of one in ten thousand, the true facts being stated on page 318, where it is shown to be less than 0·03 of an interference band, corresponding to about four wave-lengths in the final result. Not two but six counts in yellow neon light are recorded, two on each of three separate sets of Grayson-ruling (half wave-length) fiducial marks, and double this number of counts were actually made with identical results.

As regards the accuracy-test of the building-up process, the calculation of the H_α wave-length given by Mr. Sears is also unfair, as it is made clear in the paper (p. 321) that the hydrogen results are not relied on, being influenced by the fact that the red line H_α is a doublet, and therefore only used in general confirmation of the neon results. It is the final result with yellow neon Ne_c light, 1,562,409 wave-lengths in the yard, which is alone relied on, the Ne_c line being unresolvably single and its wave-length a standard constant, so that the number of wave-lengths of cadmium red Cd_r light in the yard, 1,420,210, calculated by use of this constant and the standard wave-length of Cd_r, is unimpeachable.

It is, indeed, important that the value of the yard in standard wave-lengths should be known with the greatest possible accuracy, and no one will welcome more than myself the result of the determination by Fabry and Perot's method now in progress at the National Physical Laboratory. My own being a totally different method, it must surely be an advantage if the two different methods eventually turn out to give results in practical agreement.

A. E. H. Tutton.

Electron Exchange Phenomena in the Excited Atom.

In an interesting paper recently published,[1] H. S. W. Massey and C. B. O. Mohr have calculated the relative electron excitation probabilities in the case of helium.

These calculations, while following up the previous work of Oppenheimer, Born, and Dirac, take into particular account electron exchange phenomena in the excited atom.

Their final results show that in the case of 200 volt electrons in helium the relative probabilities to be expected are as follows :

Transition .	$1S-2S$.	$1S-2P$.	$1S-3P$.	$1S-3D$.
Singlet . .	0·03	0·09	0·0015	0·00025
Triplet . .	0·001	0·00002	$0{\cdot}0_71$	$0{\cdot}0_61$

It so happens that we have been engaged in an experimental investigation involving this very point, some of our results being published in the *Proceedings of the Leeds Philosophical and Literary Society* in March 1931, and in the *Philosophical Magazine* for November 1931.

Our experiments agree, approximately at any rate, with the above results so far as the 1^1S-2^1P and 1^1S-3^1P transitions are concerned, but *we have failed to find any evidence at all of any transition corresponding to* $1S-2S$ singlet or triplet.

It is clear that we should have found it, if present, according to the relative intensity predicted by Massey and Mohr.

It may not be without interest further to point out that Jones and Whiddington[2] found that in the electron excitation of H_2 there was a marked maximum in the probability of an observed loss of about 9·0 volts in the neighbourhood of 16 volts velocity of impacting electrons. The suggestion made at the time was that this loss was an excitation resulting in the emission of the optical continuous spectrum.

This notion is strengthened if regarded in the light of the work of Massey and Mohr, since the loss in the case of H_2 seems by analogy as likely to be a triplet excitation, the continuous spectrum being produced by transitions to a supposed unstable 1^3S state.

The Atomic Weight of Fluorine.

Messrs. H. S. Patterson, R. Whytlaw-Gray, and W. Cawood have published[1] some preliminary results on a new revision of the molecular weight of methyl fluoride which seems to lead to the value 19·010 for the atomic weight of fluorine. I should like to point out that the references given in favour of this value are by no means trustworthy. In the first place, the work of McAdam and Smith[2] on the analytical ratio, sodium fluoride to sodium chloride, was a preliminary one. The only two transformations carried out give, after correction to a vacuum, fluorine = 19·019 (instead of 19·010). Smith and van Hagen[3] conclude more recently that "the experience of these authors shows that the reaction in question did not proceed smoothly", and that "the errors of experience—traces of water in sodium fluoride and conversion incomplete to sodium chloride—would have increased the value of the atomic weight of fluorine". Germann and Booth[4] have determined the normal density of silicon tetrafluoride, but, as Clarke has pointed out,[5] "do not go so far as to compute from this figure the molecular weight of the fluoride". By comparison with the deductions of Jacquerod and Tourpaian,[6] Clarke obtains for the molecular weight 104·47 and hence for the atomic weight of fluorine 19·09 (not 19·010). Van Laar, on the other hand, assuming that the critical constants for silicon tetrafluoride as determined by Moissan are incorrect, has calculated the molecular weight as 104·13 and hence they find 18·995 for fluorine.

The most recent work of Smith and van Hagen has proved that the ratio of fluorine to another halogen, say chlorine, may be established analytically much more readily by an indirect comparison—say, by converting a sample of a suitable compound to the choride and another sample of the same preparation to the fluoride by an independent method. With borax as such an intermediate compound, Smith and van Hagen have established many cross-ratios between sodium fluoride and sodium chloride, sulphate, nitrate, and carbonate. With the most probable values for chlorine, nitrogen, sulphur, and carbon we get for fluorine 19·002, 19·001, and 19·000. Only the conversion from borax to sodium carbonate, which would be incomplete, gives fluorine 19·006. The other exceedingly reliable values support the value 19·000 as found by Moles and Batuecas.[7]

Aston, using the new mass-spectrograph and with boron trifluoride, deduces 19·000 as the atomic weight of fluorine, in agreement with our conclusions.[8]

With reference to the criticisms on our work on the normal density of methyl fluoride, I should like to point out that the gas was prepared by two different methods : by the reaction of potassium fluoride with potassium methylsulphate and by the action of methyl iodide on silver fluoride. The mean values for the density from the two methods agree by 1·7 part in 10,000. For the compressibility measurements, only the gas from the second source, which will certainly not be contaminated with methyl oxide, was employed.

The method of Collie (decomposition of tetramethyl ammonium fluoride by heat) has been tested in my laboratory by Gonzalez.[9] By heating the salt to 160° over phosphorus pentoxide in a vacuum for several weeks, it was not possible to obtain an anhydrous product. Traces of water are retained by the fluoride, and by heating this salt to 180°, decomposition and at the same time a secondary reaction with production of ammonia, nitrogen oxide, and methane take place. Purification of the evolved gas with potash, ferrous sulphate, sulphuric acid, and phosphoric anhydride and repeated liquefaction and fractionation give a gas fraction with constant density and constant boiling point which contains about two per cent methane.

If we use the constant litre weight found by Gonzalez, 1·5363, and the results of Patterson, Whytlaw-Gray, and Cawood at 21°, to calculate the coefficient of thermal expansion of methyl fluoride, we get the normal value 0·0037. On the other hand, van Laar,[10] with the critical constants as determined by Collie with the impure gas, has calculated the compressibility coefficient 1·0094, which approaches the value deduced by Patterson, Whytlaw-Gray, and Cawood, namely, 1·0109. It seems very probable that the methyl fluoride used by the latter workers was contaminated with some two per cent of methane.

It appears to be highly improbable that the atomic weight of fluorine should exceed 19·000. A detailed paper will appear soon elsewhere. E. MOLES.

Respiration of Healthy and Leaf Roll Potatoes.

IN the study of virus diseases of plants, comparatively little attention seems to have been paid to the effect on metabolism. This is particularly surprising in the case of potato leaf roll where the retardation in growth, pallor of the foliage, and the accumulation of carbohydrates in the leaves at the expense of the tubers, point to the disease effecting profound changes in normal metabolism. In the belief that this modified metabolism would be reflected in the rate of respiration, a comparative study of the respiration (as measured by the weight of carbon dioxide evolved per gram fresh weight and dry weight) of healthy and leaf roll potatoes has been made at various stages in the life-cycle.

Briefly, the work has shown that the respiration of the immature healthy tuber is higher than on maturation in storage, and again rises with the development of sprouts. On the first unfolding of the leaves there is an enormous rise in the respiration rate, followed by a gradual, though slight, fall as new tubers are produced. The cycle of events is much the same in the infected potato, but with important differences in detail. The infected immature tuber respires at a higher rate than the healthy tuber when first lifted, then falling, on storage, to a level slightly below that of the healthy mature tuber. On sprouting, the respiration rate lags behind that of the healthy tuber until the sprouts break into leaf, when the great increase in carbon dioxide production noted in the healthy plant is exceeded by the diseased one. This higher rate of respiration of infected foliage is evident, therefore, before any rolling or excess accumulation of starch occurs in the leaves, but not necessarily before sugars begin to accumulate. It remains at a higher level than the respiration of the healthy plant during the rest of the growing period. It is of interest to recall that Thung, though mainly working with detached leaves floating on water, also found a higher rate of respiration in leaf roll than in healthy leaves.

Anaerobic respiration in nitrogen is unaffected by the virus; the tuber—whether diseased or not—producing 70-80 per cent of the carbon dioxide evolved under aerobic conditions. The growing plant is able to emit as much carbon dioxide anaerobically as it does aerobically, whether infected or healthy. The changes in respiration during the life of a potato could therefore be represented by much the same curve for anaerobic as for aerobic conditions. It is higher in the diseased immature tubers, about the same in diseased and healthy after prolonged storage, lower in diseased sprouting tubers, but much higher than the healthy plant once leaves have developed.

Glasshouse plants growing in pots have been used throughout this work, whilst tubers in different stages of maturity have been obtained from plants growing under normal field conditions. No explanation of these results can be offered at present, but it is hoped that further studies will not only throw some light on the nature of the metabolic disturbances caused by the leaf roll virus, but also provide a new angle from which to view the inter-relationship of respiration, available respirable material, and growth in normal plants.

Eurytemora thompsoni, A. Willey: A New European Record.

IT is a common, but none the less mistaken, conception that the be-all and end-all of the systematist is the discovery of new species. In reality, the discovery of well-known species in remote parts of the world has a far greater fascination and is infinitely more important. It is perhaps no exaggeration to state that the world-wide distribution of common species of animals and plants is the basis of one of the most fundamental conceptions of the whole of the science of biology, since on it rests almost our only data for observing the influence of environment.

In June of the present year, on visiting a brackish-water pool, removed but not far distant from the sea at South Lancing, Sussex, I came across numerous specimens of a species of *Eurytemora*, a well-known genus of copepod.

Close investigation showed that the species was not British or even European, and it was, in fact, *Eurytemora thompsoni*, Willey, of which no other record existed beyond that of Prof. Arthur Willey, of McGill University, who took it from the stomach of a fish caught in a weir near the low-tide level at Scotsman Bay, Nova Scotia.

The species had also been found, but not recorded so far, by Prof. Smirnov, of Leningrad, in the brackish waters of the Sea of Okhotsk. A truly remarkable distribution as it stands, but it is more than likely that the species exists in many other brackish-water localities, but so far it has escaped detection.

A full description of the species has just been published in the November part of *Annals and Magazine of Natural History* A. G. LOWNDES.

Uteroverdin.

ONE of us [1] has recently isolated oocyan—the blue-green pigment of the shells of many birds' eggs—and characterised it as an ether-soluble pyrrol pigment closely related to the bile pigments. We have now found a second example of this class of substances in the green pigment of the dog's placenta, the properties of which are very similar to those of oocyan. This pigment was examined in 1871 by Etti,[2] and considered to be biliverdin; it is formed by the transformation of the blood-pigment in the extravasates of the dog's placenta.[3] While the methoxyl content of the ester of oocyan indicated a molecule with only three pyrrol nuclei, the analysis and methoxyl content of the methyl ester of uteroverdin (as we will call the substance) show that we are dealing with a substance with four pyrrol nuclei. From its composition ($C_{35}H_{38-42}N_4O_6$) it appears that it is the dimethyl ester of a dehydrobilirubin or dehydromesobilirubin. The values for C, H, and N (not, however, the methoxyl content) of the ester of oocyan agree also with the formula $C_{37}H_{42}N_4O_8$; that is to say, with that of the trimethyl ester of a substance which differs from uteroverdin only in possessing one more carboxyl group. A further investigation of oocyan by one of us (R. L.) is in progress.

Oocyan differs from the synthetic tripyrrenes of H. Fischer[4] in its absorption and in giving a clearly positive Gmelin reaction. Attempts are being made to pass from bilirubin to this new class of substances, to which probably belong one or other of the green oxidation-products of bilirubin, obtained by very different methods, hitherto considered to be 'biliverdin'.

We do not know yet what is the significance of the fact that the decomposition of hæmoglobin in the dog's placenta—and in other cases of blood extravasates in the uterus—leads to such pigments instead of to bilirubin. It has not, up to the present, been possible to demonstrate an enzymic formation of uteroverdin by placenta tissue or tissue extract, any more than in the case of bilirubin.

Properties of Aerosols.

MESSRS. W. Cawood and H. S. Patterson's letter[1] describing "A Curious Phenomenon shown by Highly Charged Aerosols" is very interesting from the viewpoint of spontaneously electrified aerosols, as well as from that of aerosols electrically charged from an independent source such as they used.

The work of W. A. D. Rudge,[2] showing that most aerosols initiate static charges owing to the movement of the constituent particles through the gaseous dispersion medium, has led to the theory of A. Stager,[3] who experimented with driven snow-dust on the Jungfrau, that in a spontaneously charged aerosol the smaller particles become charged in one sense and the larger ones in the other sense. On *a priori* grounds this theory does not seem capable of satisfying the facts save where the disperse phase of an aerosol consists of particles of but two sizes. For, where particles of several sizes were involved, any dimension except the smallest and largest would be both 'larger' and 'smaller' by alternative relation with respectively juxtaposed sizes. On the other hand, the phenomenon observed by Messrs. Cawood and Patterson seems to confirm selectivity of charge-sign dependent on variation in particle size in so far as electrification due to an independent source can be compared with self-electrification of an agitated aerosol.

In Messrs. Cawood and Patterson's experiments both types of electrification would, presumably, exist, and although one does not know what degree of spontaneous electrification would arise on, say, *p*-xylene-azo-β-napthol under the conditions they imposed (Blacktin and Robinson[4] find that 0·0011 oz. av. per cubic foot of coal dust of fineness 83·5 per cent through 200 I.M.M. sieve, whirled at 45 feet per second, rapidly initiates a potential of more than 4000 volts), it may well be that 'clusters' might be formed in their chamber, (*a*) merely on fanning without independent electrification, or (*b*) partially due to the additional spontaneous electrification as a significant superposed factor. If the former proved correct, a great step would have been taken in establishing the sign-particle size theory of spontaneous electrification in aerosols.

It may be worthy of note that if, as Messrs. Cawood and Patterson suggest, globular lightning may owe its origin to an effect analogous to the phenomenon they observe, the "very much higher potential" involved would be of spontaneous, rather than independent, origin. This would be a tentative reason for expecting the phenomenon they observed to show itself as producible merely through controlled spontaneous electrification without the necessity for introducing an independent source of electrification.

Carbon Contacts.

IN his delightful article on the Hope-Jones clock, in NATURE of Oct. 17, Prof. Boys refers to the difficulty of obtaining sure and certain contact for electrical purposes with light pressure. This difficulty may be overcome by using carbon contacts. I have had a station voltage regulator in operation for some twenty years with carbon contacts and the result has been quite satisfactory, the carbon being pure and free from ash. The microphone provides another instance of such contact operated in circumstances which are delicate. Probably there are many instances in the laboratory where carbon contacts for working apparatus through relays would be of service.

C. TURNBULL.

Electricity Works,
North Shields, Oct. 31.

THE contact difficulties to which I referred were those of fifty years ago with light or hesitating contacts backed by insufficient volts. I did not intend to imply that at the present time with new materials and abundant volts contacts need give any trouble. I have for a long time recommended Acheson graphite made at Niagara, from which all other matter has been volatilised, and this, I expect, is what Mr. Turnbull has used. There are also the more modern mercury in nitrogen contacts which are admirable where the larger movement necessary to operate them and the slight time delay do not matter.

Where there is much self induction in the circuit to be broken, plenty of capacity as a shunt across the break is desirable, and thanks to wireless dealers this can now be obtained for fewer shillings than the cost in pounds at the earlier date. I used at Oxford when weighing the earth in place of a capacity a pair of electrolytic cells in series with platinum electrodes which I still have, the current coming from a pair of secondary cells. At each break every second a bunch of microscopic bubbles of the electrolytic gases were evolved, but the spark was absolutely quenched. Such a device is the electrical analogue of the water ram. Not one contact ever failed. I consider it better than a true capacity.

C. V. BOYS.

Electrical Conditions in Stratified Clouds.

IN preparing a paper on "The Physics of High Altitudes" for the Dublin meeting of the British Association in 1908 (Climate and Health Committee), I spent some days on one of the central heights of Madeira observing atmospheric electrical conditions during the placid season of summer weather.

The wind was steadily N.N.E., and except for ascending masses of vapour the inflowing sea-breeze from solar generation had wasted before reaching my station 5700 feet from the sea. The mountain collar cloud formed with great regularity, and varying slightly with barometric pressure became a stationary mass, perhaps 500 feet thick, at an altitude between 2500 feet and 3000 feet.

The upper surface waste of constant evaporation was steadily recuperated by the arriving cloud vapour, visible or condensed, which spread out as a lower layer of the collar.

Now this collar cloud took, always in calm weather, a distinctly stratified form, and on one or two occasions when in exceptionally high barometric conditions the collar rested at an unusual height—6000 ft. or 7000 ft.—I was able to fly my kites into close proximity with the arriving vapour masses which were to maintain the collar in structure and position.

These arriving masses were always electrified, that is, clothed with an envelope of positive electricity varying in intensity as indicated by Thomson's portable electrometer, to which my kite was attached by a wire conductor twisted with the string; and the vapour masses, thus clothed, seemed on arrival at the cloud under-surface, itself positively electrified, to hesitate and to be kept apart, thus giving a clue to the stratified appearance which it is here my object to illustrate.

By and by distinct coalescence would occur, but the cloud never lost entirely the stratified arrangement of its component layers. My kites were made of thin glazed lining, for paper would collapse under aqueous vapour, and I was able, with an improvised oiled silk receptacle fitted with spirit and provided with a spreading unlighted wick, to provide the waste of substance accomplished by the burning match or water dropper.

MICHAEL GRABHAM.

Madeira, Oct. 6.

The Band Spectrum of AsH.

THESE bands were obtained by photographing a carbon arc, the negative electrode of which had been drilled and filled with arsenic, run in an atmosphere of hydrogen at a potential of 110 volts. No bands were obtained with the arsenic in the positive electrode. The electrodes were composed of Acheson graphite. The spectrograph used was a Hilger three-metre quartz prism instrument.

Three bands were found. Two, the origins of which were at 32,380·2 cm.$^{-1}$ and 31,636·9 cm.$^{-1}$, had very wide spacing between the lines, and appeared to be typical hydride bands. The other band was unresolved and was probably due to As_2. The head of the band was at 31,802·6 cm.$^{-1}$.

The AsH bands were shaded to the red and consisted only of *P* and *R* branches. The lines of the band at 32,380·2 cm.$^{-1}$ were fitted by the formula

$$\nu = 32{,}380{\cdot}18 - 11{\cdot}186\, M - 4{\cdot}474\, M^2 + 0{\cdot}0485\, M^3 + 0{\cdot}01027\, M^4,$$

but since the origin lies in the head of the band we have not yet been able to assign definitely the true quantum numbers. There was no sign of doubling in any of the lines. The electronic transition is, therefore, probably of the type $^1\Sigma - {}^1\Sigma$.

The other hydride band is badly confused by the As_2 band, and no analysis has yet been attempted. Further work will be carried out in the near future.

Branching of Lightning.

SCHONLAND and Allibone, in NATURE of Nov. 7, contribute what seems to be conclusive instrumental evidence that lightning discharges proceed from a negatively charged cloudbase. Confirmation (if any were required) may be obtained optically by the observation of very distant flashes, on the assumption that lightning consists primarily of direct electronic movement.

If the discharge is sufficiently far away, the subtended angular motion is so small that it is possible, in the duration of the flash, actually to see which way it is moving. I have noted several such discharges, particularly under the favourable conditions prevailing in sub-tropical China, and in every case the flash could be seen to start from the cloud and 'grow' downwards.

Esperanto in Scientific Literature.

UNTIL quite recently the use of Esperanto for scientific purposes was usually regarded as a matter of jest. This is still the attitude of many who, while they readily appreciate how immensely valuable an easy but complete, precise, and euphonious international language would be, do not realise that Esperanto not only possesses these claims in theory, but has also been tried out in practice with most encouraging results. Several entire papers have been published in Esperanto from the Institute of Physical and Chemical Research at Tokyo, and other Japanese (and also European) institutions issue bulletins in this language. Esperanto may certainly be considered a satisfactory medium for composition on physical and chemical themes, as during the last three decades various commissions, societies, and individuals have carried out translations and compiled lists of technical terms which have been officially accepted. Consequently, a complete system of chemical nomenclature and a very complete physical and chemical vocabulary have now been available for several years.

An efficient medical language has been developed lately through an international society of medical men, and a monthly review which has flourished since 1923. In the more general field of biology, however, the language has been much less widely employed, though here again various individuals have performed notable spade-work in the compilation of technical vocabularies and in working out systems of nomenclature. A group has recently been formed to take stock of the existing material and to develop its use by the translation of biological papers. I shall be glad to send particulars to anyone interested in the subject.

R. M. MORRIS-OWEN.

Folk-Tales of the Cochita, New Mexico.—A collection of tales told among the Cochita Indians of New Mexico, collected by Ruth Benedict, is published as *Bulletin* 98 of the Bureau of American Ethnology. As the tales were recorded in a house open to all, they form a selected group; for there is a taboo against telling certain tales to whites, just as there is a taboo against whites seeing masked dances or dancers. The tales fall into certain classes, such as stories of the katcinas, hero tales, true stories, and the like. Some are obviously of European origin; but the great majority are fictional. Under the influence of the study of the European folk-tale, which is obsolete, the significance of the fictional story among primitive peoples is often overlooked. The fictional story, notwithstanding its imaginative character, deals with incidents, situations, and problems which are real in the culture of the people. Among the katcina stories, that of the quarrel between two sisters is the origin story of the Cochita; but owing to the prejudice against telling it to the whites, only the culminating incident is given. In the hero tales, the heroes are insignificant, poverty-stricken, and ridiculed boys who are successful in overcoming their enemies and mockers. The Twin Heroes, the protectors of the helpless and the institutors of custom, are mischievous and irresponsible; the Arrow Boy does not hunt and spends all his time courting girls; the Poker Boy is ugly and untidy, and so forth. Montezuma, though a mythological culture hero, is ridiculed as a half-wit. The novelistic tales are fictional versions of Pueblo life, excepting in two respects, one difference being a contest over food stores, the other, marriage to multiple wives, polygamy being absent both in the old culture of the Cochita and at the present time under Roman Catholic teaching. Throughout the stories, the initiative and independence of the women is strongly marked.

Song of an American Oriole.—From observations made in the neighbourhood of Pinole, California, Alden H. Miller is of opinion that his countrymen have not given proper credit to the song of Bullock's oriole, *Icterus bullocki* (*Wilson Bulletin*, June 1931). At any rate he gives an interesting story of the relationship of the song to territorial claims. In spring the male bird precedes the female by one to two weeks, and establishes a singing post. When the hen arrives she combines in the defence of the territory, but the cooperation is imperfect until the nest is built, in the sense that the hen drives away females only, and the cock, males only. Indeed, the female during this period may actually court strange males in the reserved territory (which scarcely seems to be playing the game), but the attachment of the male is equally diffuse. The song of the hen oriole in defence of the territory and in association with males is in every way comparable to the songs of the cocks, and may be regarded as a true territorial song. The songs of the sexes are similar in rhythm, pitch, and quality, except that the final notes of the female's song are slightly harsher, of somewhat less range, and show modifications of rhythm. Before or during nest-building the songs of females may, on occasion, be even more abundant than the songs of the males.

Musculature of Crustacea.—The main portion of the Report for 1930 on the Lancashire Sea-Fisheries Laboratory at the University of Liverpool edited by Prof. James Johnstone and Dr. R. J. Daniel (Liverpool University Press: 1931), is taken up with a continuation of Dr. Daniel's researches on muscles of certain Crustacea: "The Abdominal Muscular System of *Homarus vulgaris* (L.) and *Palinurus vulgaris* (Latr.)": "The Abdominal Muscular System of the Shore Crab (*Carcinus mœnas*) and of the Zœa I and Magalopa Stages": and "Comparative Study of the Abdominal Musculature in Malacostraca. Part I. The Main Ventral Muscles of the Typical Abdominal Segments." In this last paper the author compares all the types investigated both in the present work and in previous reports. *Paranaspides lacustris, Praunus flexuosus, Meganyctiphanes norvegica, Crangon vulgaris, Homarus vulgaris,* and *Palinurus vulgaris* have all been examined. The main conclusions are that the ventral muscles of the Decapoda chosen may be derived from the Paranaspides type by the addition of true transverse and dorso-lateral muscles; those of *Praunus flexuosus* and *Meganyctiphanes norvegica* being very much specialised. In the case of *Carcinus mœnas* it was found that both in the first zœa and in the megalopa the musculature of the abdomen is very simple and anticipates that of the adult crab, where the abdomen is so much reduced.

Respiration of Wheat at Low Temperature.—The commercial importance of frost resistance in Canadian agricultural practice has led recently to a large number of studies of the physiological mechanism underlying hardiness or resistance to frost injury. Newton and Brown (*Canad. Jour. Research*, 5, 333) have investigated the degree of catalase activity shown by juice pressed from wheat plants of various hardy and non-hardy varieties. Under the conditions employed, the activity is greatest in the juice of hardy plants. On the other hand, a subsequent investigation of the rate of respiration of similar varieties of wheat by Newton and Anderson (*Canad. Jour. Research*, 5, 337) showed that the plants of hardy varieties have a smaller respiration rate at temperatures below the freezing point, which agrees with a previous observation that their reserves of sugar are maintained at a higher level during winter than are those of non-hardy varieties. The difference in respiration rate is not, however, observed at higher temperatures.

A Satellite Missing from Ever-Sporting Stocks.—A cytological study of certain ever-sporting races of garden stocks—singles which throw doubles—by Dr. J. Philp and Prof. C. L. Huskins (*Jour. of Genetics*, vol. 24, No. 3), has revealed a striking explanation. The strains were obtained from Miss E. R. Saunders, who has done much genetical work on the genus. Examination of the somatic chromosomes ($2n = 14$) shows that one pair (A) in the pure single and pure double strains has a subterminal fibre-attachment constriction and a trabant or satellite attached to the short arm. In ever-sporting singles one of the A chromosomes lacks the trabant. Such plants are heterozygous for the recessive doubleness, these factors being carried in the A chromosome but not in its satellite. Pollen grains which contain the chromosome lacking the satellite do not function in fertilisation, while this condition is lethal in only part of the female gametes. On this basis the long-known ever-sporting behaviour is explained in general accord with Frost's earlier hypothesis. The authors also show that in a trisomic mutation called 'Crenate' by Frost, which behaves as a trisomic for singleness-doubleness, three A chromosomes are present, two of them having a satellite. Frost's variety 'Snowflake' and its trisomic mutants are found to have long meiotic chromosomes, a confirmation of observations by Lesley and Frost. It is suggested that this condition has arisen from the normal by a mutation which delays slightly the onset of chromosome contraction in the heterotypic prophase.

Timber of the British Douglas Fir.—*Bulletin* No. 10 (August 1931) from the Forest Products Research Laboratory at Princes Risborough treats of the timber of home-grown Douglas fir, now termed *Pseudotsuga taxifolia*, following the International Rules of Botanical Nomenclature, instead of *P. Douglasii*, the name which has been so long in use in Europe. The bulletin has been written by Mr. B. J. Rendle, and comprises the investigations carried out by him with the view of indicating "to growers and users the possibilities and limitations of the timber". Mr. Rendle's investigations have shown several most interesting and reassuring factors on the subject of the home-grown wood of Douglas. The logs investigated came from Benmore and Kilmun in Argyllshire, Taymount in Perthshire, Longleat in Wiltshire, and Highclere in Hampshire. The age of the trees varied between fifty and sixty years, except in the case of Highclere (thirty-five to forty years). This implies that in no case had the trees reached maturity, and consequently contained a high proportion of the rapid-grown timber of the early years as compared with the slower-grown material of later life. It is believed from the examination of the latter that maturer trees would show a greater percentage of the better-class timber. The wood can be readily seasoned, both in the open and in the kiln. For the private proprietor of woods an important outcome of the tests has been that Douglas pit-props have approximately a strength equal to home-grown Scots pine and to that of imported Baltic and French timber, and this in spite of the rapidity of growth in early years. This rapid growth and the question of slowing it down in order to obtain a larger number of rings to the inch (not less than six or seven and preferably ten) is one of the economic problems which will require settlement according to the objects for which the woods are formed: that is, to give a quick and early return, to provide as large an amount of mature timber as possible, or to achieve a middle course. It is mainly a sylvicultural problem. Mr. Rendle's study has been systematic and thorough. The bulletin deals with investigations on structure, seasoning, strength, preservation, working qualities and grade, and uses.

Southern Rhodesian Geology.—The geology of the country around the well-known Shamva Mine, north-east of Salisbury, is described by R. Tyndall-Biscoe in *Bulletin* 18 of the Geological Survey of Southern Rhodesia (pp. 87 and geological map, 1931). The greater part of the area is made up of Archæan rocks, the oldest of which consist of highly metamorphosed basic volcanic rocks (greenstones) with interbedded strips of recrystallised sediments. The "Shamva Grits" follow, including arkoses and greywackes, and conglomerates that carry pebbles of the older series. Both sets of basement rocks are invaded by gneissic granite and associated intrusions. It is fairly well established that the gold-bearing quartz-reefs and other gold deposits of the region are to be correlated with the later stages of this igneous cycle. It is concluded that the gold of the Shamva Mine was originally a constituent of the magma which solidified to form the two granite stocks now exposed to the north-east and south of Shamva. The next recognisable episode was the intrusion of dolerite dykes and sills. In part these belong to the late Karroo, but as dykes of three or four different ages are known it is likely that some were injected during earlier geological periods. An excellent series of chemical analyses by E. Golding deserves special mention. These continue to confirm a geochemical generalisation that has already been noted in these columns, namely, the unusual abundance of strontium and paucity of barium in the rocks of Southern Rhodesia.

Atmospheric Ionisation.—Prof. J. J. Nolan and Dr. P. J. Nolan have published in the *Proceedings of the Royal Irish Academy* (vol. 40) an account of their observations on the state of ionisation of the air at Glencree, in the Wicklow hills. This station can be regarded as uninfluenced by large towns, except when the wind blows directly from Dublin, and to a less extent from smaller places to the east. The data obtained for different winds thus provide information about both clean and contaminated air, and show clearly the effect of the city in producing condensation nuclei, probably products of combustion, in large numbers. The smaller ions are less affected, and after eliminating, so far as possible, all disturbing influences, it was found that about five hundred were present in a cubic centimetre with a positive charge, and 375 with a negative charge; the disparity of the concentrations was diminished by rain. The ratio of concentrations also shows a diurnal variation corresponding to that of the vertical field in the air, and there is evidence that the rate of formation of ions fluctuates in a similar way. An appendix to this paper contains the results of all the observations made between October 1928 and December 1930, and should prove valuable for comparison with readings taken at other stations.

Distillation of Dry Liquids.—It has been observed by several investigators that dry liquids boil with difficulty. The abnormal behaviour observed with liquids after intensive drying might be due, in part at least, to the slowing down of the rates of evaporation and condensation of liquids after such treatment. In the October issues of the *Journal of the Chemical Society*, J. W. Smith records experiments with intensively dried ethyl bromide. This was contained in a bulb connected with a second empty bulb, a wide tube containing phosphorus pentoxide being sealed to the tube connecting the first two bulbs. In this way no obstruction to the vapour was introduced. All air was removed from the apparatus. It was found that the time of non-ebullitional distillation increased markedly with drying, and it was difficult to obtain ebullition with the very dry liquid even with violent shaking in a bath at quite a high temperature. The effect was not removed by a period of heating of the liquid, which is considered to indicate that polymerisation is probably not responsible for the change, since this polymerisation might be expected to be broken down by heating. No change in the vapour pressure of ethyl bromide due to intensive drying could be detected, this result being in contradiction to those of Smits, who found an increase, but after a longer period of drying than that used by Smith. No separation into fractions by distillation could be achieved. The change in rate of distillation is very slight in the first period of the drying, but then increases sharply, afterwards decreasing again. The results are interpreted as showing that intensive drying does not disturb the internal equilibrium of a liquid, but that the effects are due to some form of superheating, probably induced by the removal of nuclei of some type during the treatment with phosphorus pentoxide.

Heat Insulation of Furnaces.—The issue of *Chemical and Metallurgical Engineering* for July contains an account by Messrs. J. B. Barnitt, research engineer of the Aluminium Company of America, and R. H. Heilman, fellow of the Mellon Institute of Industrial Research, of their search amongst the aluminium compounds for a material which would withstand temperatures of the order of 1000° C. and at such temperatures have a low heat conductivity. They find that aluminium monohydrate, bauxite monohydrate, and a waste product from the extraction of pure aluminium material from bauxite are the most promising materials, and that their heat conductivities, which all increase with rise of temperature, are in the ratios of 15 : 9 : 6. The latter is cheap but heavy, the bauxite monohydrate is less expensive than the aluminium monohydrate, but will not stand such high temperatures as the latter. If the heat insulating material is required in brick form and not as a powder, the authors find that bauxite monohydrate, with certain additions to increase its strength at high temperatures and decrease its shrinkage, is best, and blocks of this material 12 in. by 36 in. and of various thicknesses are now on the market.

Distance Thermometers.—In an illustrated pamphlet of 40 pages, Messrs. Negretti and Zambra discuss the relative merits of gas, vapour, and liquid thermometers for use at a distance from the observing station, and come to the conclusion that mercury in steel thermometers with dial scales are the most serviceable. The errors to which such thermometers are subject are considered, and conclusions are drawn as to the best methods of eliminating them. The capillary tube connecting the bulb to the Bourdon tube which carries the pointer has its bore reduced to 0·005 in., so that the error due to it may in most cases be neglected. Fatigue of the Bourdon tube material has been overcome by the use of a special steel and a section which distributes the stress in the material more uniformly.

Astronomical Topics.

The Leonid Meteors.—A Science Service bulletin, dated Nov. 16, reports a fairly active shower of these meteors in the early hours of Nov. 16, observed by seven students of Columbia College, Dubuque, Iowa, under the direction of Rev. J. Theobald, professor of mathematics. In spite of a slight haze, 289 meteors were observed in six hours; the maximum rate of fall was 90 per hour at 4.45 A.M. (that is, 10.45 U.T.). These meteors came about eighteen hours before the slightly less active shower observed in England by Mr. Prentice and Mr. King.

Drs. Johnstone Stoney and Downing, in their work on the return of the meteors in 1899, introduced the terms "ortho-Leonids" and "clino-Leonids"; the former are a comparatively compact clump, which are seen only in the years round about the comet's perihelion-passage. Since the earth takes only five or six hours to traverse the ortho-stream (Olivier, "Meteors", p. 36), one or other, or perhaps both, of the displays described above must have belonged to the clino-Leonids; these are scattered around the whole of the long elliptical orbit, but more thickly in the neighbourhood of the comet. When the ortho-stream is entered, the hourly rate sometimes goes up to thousands. Even in the comparatively poor displays of thirty-three years ago, 800 meteors were recorded in a few hours, both in 1898 and in 1901.

Father O'Connor reports that arrangements were made at the Stonyhurst College Observatory to keep the sky under observation during the nights of Nov. 15–18. Rain or clouds prevailed almost the whole time, but it cleared up somewhat about 4.0 A.M. on the morning of Nov. 17. "Between 4.15 A.M. and 6.0 A.M. I observed 13 Leonids, of which four, observed at 4.32, 5.2, 5.3, and 5.42, were considerably brighter than first magnitude stars. The one at 5.3 in particular was exceedingly bright, and distinctly illuminated the surrounding country."

The Mass of Saturn's Ring.—H. Slouka contributes a paper to *Scientia* for August in which he traces the history of investigations on Saturn's ring, beginning with Galileo's well-known anagram announcing the triple nature of the farthest planet. Next comes Cassini's detection of the great gap in the ring, and Laplace's investigation of its stability. Bessel was the first to make any attempt to determine the mass of the ring, which he did from the observed motion of the apse of Titan's orbit: he gave the two values 1/213 and 1/118 of Saturn's mass; both are now known to be much too large, and his revision made things worse instead of better. Clerk-Maxwell, after proving that the rings must be composed of cosmic dust, made an estimate of the number and size of the particles, from which he deduced the very low value 1/50,000,000 for its mass. Tisserand, from the motion of the apse of Mimas, found the large value 1/620; Meyer revised Tisserand's work, using improved values of the constants; he first gave 1/1960, but reduced this later to 1/26,700. H. Struve's exhaustive researches on Saturn's system are well known; he found it impossible to assign an accurate value for the ring's mass; he proved that it could not exceed 1/314, but regarded 1/26,700 as more probable.

The estimate which H. Slouka considers the most reliable was made by Louis Bell from a study of its albedo, based on the photographs taken by Wood in 1916 in light of different wave-lengths; he deduced that the thickness of the rings does not exceed 15 km., and is still less in the less luminous regions; he gave 1/1,000,000 as a maximum value of the mass.

The general conclusion is that an exact determination of the mass is impossible, but that most of the gravitational determinations are much too high. The research is made more difficult by the fact that the polar flattening of Saturn acts on the satellites in the same manner as the ring, but with much greater effect.

Theories of the Birth of the Planetary System.—Most upholders of the tidal theory postulate that another sun made a near approach to our own, and that its immense tidal action caused a filament of matter to leave the sun, which afterwards broke up into the different planets. Dr. H. Jeffreys suggested, a year or two ago, that an actual collision of the two suns would give a better explanation of some features of the solar system. A report by Science Service, Washington, D.C., dated Oct. 27, describes a lecture given to the Washington Academy of Sciences and the Society of Sigma Xi, by Prof. Willem de Sitter. He prefers the collision theory to the purely tidal one, on the ground that it gives an easier explanation of the rotations of the sun and planets. He supposes that in addition to the matter of the planets there was a large amount of diffused gas expelled from the sun. Much of this was later reabsorbed by the sun, but it had in the meantime acquired moment of momentum from the other star, which it imparted to the sun in the form of rotation. The gaseous medium also helped to make the planetary orbits more circular.

Anniversary Meeting of the Royal Society.

SIR F. GOWLAND HOPKINS delivered his first anniversary meeting address as president of the Royal Society on Nov. 30. Referring to the Society's activities during the past year, Sir Frederick remarked that the Council is well satisfied with the change of policy initiated last year, whereby it was decided to expend accumulated trust funds on the active support of current fundamental researches. While the Council no longer has accumulated funds at its disposal, it is proposed to do all that is financially possible in support of individual research.

This year the following grants have been made: From the Messel Fund: £800 a year for five years to Dr. Honor B. Fell, of the Strangeways Research Laboratory, for the support of her valuable work on tissue culture; also £150 for the current year, and, after the termination of his 1851 Exhibition Scholarship, £600 a year for two years, to Dr. M. L. Oliphant, of the Cavendish Laboratory. From the Caird Fund: £2200 to Prof. O. W. Richardson for the purchase of optical apparatus of high resolving power. From the Donation Fund: £400 to Dr. L. S. B. Leakey towards the cost of his East African Archæological Expedition. From the Darwin Fund: £500 a year for four years to Mr. C. S. Elton for research on wild vole populations, together with an additional grant of £250 for capital outlay and field equipment. Dr. S. Adler's researches on kala-azar continues to receive support from the Anonymous Bequest Fund.

During the year the Society has received three bequests—£10,000 under the will of Sir Otto Beit, £3000 from the estate of Dr. A. Muirhead, and about £250 from that of Dr. C. W. Andrews. These bequests were left without restrictions, and have been added to the General Fund.

Sir Frederick also stated that arrangements have been completed with the University of Cambridge for building and equipping a cryogenic and magnetic research laboratory at Cambridge, towards which the Royal Society is contributing £15,000. The laboratory will be known as the "Royal Society Mond Laboratory" as an acknowledgment that the Society was able to forward the enterprise through a benefaction received from Dr. Ludwig Mond.

We print below extracts from the remarks made by the president in bestowing the Society's medals.

Presentation of Medals.

COPLEY MEDAL, AWARDED TO SIR ARTHUR SCHUSTER.

Sir Arthur Schuster was the first to show the important information to be got by measuring quantitatively the magnetic deflection of cathode rays. He showed how, by combining this measurement with the potential difference which generates the rays, it was theoretically possible to determine without ambiguity the velocity, and the ratio of charge to mass, of the particles constituting the corpuscular stream. We owe to him other almost equally fundamental contributions to the study of electric discharge in gases. Thus, he showed that the passage of a luminous discharge put the gas temporarily into a conducting state, due to the presence of charged ions: these ions were able to diffuse into a space screened from the discharge by a wire gauze partition, and they could then be put into evidence by showing the conductivity of the gas under electromotive forces of a fraction of a volt. Sir Arthur was the first to show by experiment that in Crookes's radiometer the reaction was not on the sun but on the glass case of the instrument, thereby connecting the action with the residual gas. He has also made many important contributions to terrestrial magnetism. In spectroscopy he formulated independently the Rydberg-Schuster law. He invented the periodogram method of looking for periodicities in statistical material, a method which has been widely adopted by workers in many branches of inquiry, extending even into economics.

ROYAL MEDAL, AWARDED TO SIR RICHARD GLAZEBROOK.

For fifty years Sir Richard Glazebrook has been closely identified with research on physical standards, and particularly electrical standards. For many years he conducted researches associated with the absolute measurement of resistance, current, and inductance, and the results of this work is reflected in the present remarkable accuracy of electrical measurements. The name of Sir Richard Glazebrook is also world-known on account of his directorship of the National Physical Laboratory; it is largely due to his influence on the researches at that Institution that aeronautical science has made such vast progress. Physical science is also indebted to him for that great work, the "Dictionary of Physics", and in international science he has played a conspicuous part.

ROYAL MEDAL, AWARDED TO PROF. W. H. LANG.

Prof. Lang's work on the fossils of the Old Red Sandstone is of high scientific importance. It has led to the discovery and description of a new and unexpected group of plants in which root, stem, and leaf are not differentiated. For the first time it thus becomes possible to trace in a circumscribed group the probable origin of these structures from a source in which they did not exist as distinct members. The work was begun in collaboration with the late Dr. Kidston, and continued by Prof. Lang after the death of his colleague in 1924. Prof. Lang's previous intensive studies on the morphology of the liverworts and ferns had eminently fitted him to provide a morphological point of view which has given most important results.

DAVY MEDAL, AWARDED TO PROF. A. LAPWORTH.

Prof. Lapworth's work has been largely concerned with the application of physical methods to the investigation of the reactions of organic chemistry. His study of the bromination of acetone yielded results of primary importance in relation to the reactivity of carbonyl compounds and has formed the basis of many subsequent investigations. His researches on the addition of hydrocyanic acid to organic compounds, besides leading to results of theoretical and synthetical importance, made clear the mechanism of the formation of cyanhydrins. His investigations of the effect of small quantities of water in diminishing the activity of acids in alcoholic solution indicated the existence of the oxonium ion and added considerably to our knowledge of catalysis by acids. Among his more notable synthetical achievements are the synthesis of zingerone, derived from the pungent principle of ginger, and of homocamphor. His work on the mutual influence of groups in the same molecule, his recognition of induced alternate polarity, and his classification of reagents as anionoid or kationoid have played an important part in the development of the present state of knowledge of the reactivity of organic compounds.

SYLVESTER MEDAL, AWARDED TO PROF. E. T. WHITTAKER.

Prof. E. T. Whittaker is one of the best known of British mathematicians, his work showing extraordinary versatility. He has written five books, on entirely different subjects, and numerous papers which touch on almost every branch of mathematics. All his books show, besides their more technical qualities, powers of arrangement and exposition of a most unusual order; and the "Modern Analysis" and "Analytical Dynamics" have had a considerable influence on mathematical thought. Prof. Whittaker has made important additions to the theory of the solution of differential equations, ordinary and partial, by definite integrals; to the theory of Lamé and Mathieu functions, the functions of the elliptic and parabolic cylinders, and the integral equations associated with them; to the theory of interpolation; and to the theory of the solution of dynamical problems by trigonometrical series. He has also in recent years made a number of interesting contributions to the pure mathematics of relativity, electromagnetism, and quantum theory.

HUGHES MEDAL, AWARDED TO PROF. W. L. BRAGG.

Prof. Bragg's recognition of the fact that the Laue diffraction spectra could be considered as produced by reflection from the planes of the crystal lattice, besides being a great simplification of a difficult geometrical problem, was the starting-point of two important and fruitful lines of physical investigation, namely, the measurement of X-ray wave-lengths and the elucidation of crystal structure. Work on the first of these led to Moseley's discoveries and their subsequent developments. Bragg's concentration on the second has resulted in a wonderful extension of our knowledge of the structure of crystals, both simple and complex, and of inter-atomic distances and linkages. His work may truly be said to have laid the foundations of a chemistry of the solid state.

The Wellcome Research Institution.

ON Wednesday, Nov. 25, Lord Moynihan of Leeds, president of the Royal College of Surgeons, laid the corner stone of the new buildings for the Wellcome Research Institution, which are to occupy a site at the corner of Euston Road and Gordon Street, immediately north of University College.

The architect is Mr. Septimus Warwick, F.R.I.B.A., who has designed the building to meet the requirements of the different research laboratories and museums. The building materials are practically all of British origin.

Lord Moynihan, in the course of his remarks, outlined the development of the various research laboratories and museums founded by Dr. Wellcome, who, in the year 1894, founded his laboratories for physiological research, which were followed two years later by laboratories for chemical research.

On the recapture of the Sudan by Kitchener, Dr. Wellcome was one of the first civilians to visit that country, and he there saw, and for some time watched, conditions as they then were; and he found great opportunities for public service. It was in the year 1899 that he founded the Tropical Research Laboratories in Khartoum, the first director of which was Sir Andrew Balfour, who served there for twelve years. Attached to that research institute was a floating laboratory, which cruised through all the waterways of the Nile within reach, giving the opportunity there for continued research, and for carrying the benefits of research to the people who live far south.

Dr. Wellcome's activities continued also in Great Britain. In the year 1913 he established the Bureau for Scientific Research, and the Historical Medical Museum. In 1914 he established the Museum of Medical Science, including Tropical Medicine and Hygiene, and in 1920 he founded the Entomological Field Laboratory. All these institutions, or many of them, suffered, however, under one great disadvantage, which all research students will appreciate at once: they were separate from one another, giving no opportunity for that hour to hour, or minute to minute, consultation which is one of the great advantages of having collective research under one roof; but from to-day we see the possibility of that being altered. Under the roof of the Wellcome Research Institution the following subjects are to be studied: medical zoology, parasitology, entomology, tropical medicine and hygiene; there will be physiological and chemical research laboratories, the historical medical museum, and a museum of modern medicine. It will be agreed that this is a formidable and very impressive list. Dr. Wellcome's activities, however, have not been confined to Great Britain. He also gave great help towards the foundation of the Gorgas Memorial Laboratory, near the Panama Canal.

One of the conspicuous features of Dr. Wellcome's life-work has been at once its relevance and its opportunism. In all his investigations of tropical diseases he begins in an almost virgin country, and the harvest gathered has been such that not only have many lives been spared and much suffering saved, but also vast tracts of country have, for the first time, been made fit for human habitation.

At home, as all of us will agree, the great need of medicine to-day lies in the direction of increasing the opportunities for medical research, and not less in the opportunities for creating those competent to undertake medical research. Physical observation alone, from the time of Hippocrates through our great students, Sydenham, Addison, and James Mackenzie, has revealed many secrets which have been so long hidden in connexion with diseases that lay within the orbit of pure investigation, and the conquests of mere observation have been innumerable and of a value beyond all reckoning. Upon it a virile and beneficent art has found its opportunities extended and its thought affected by the encouragement and adoption of methods which are seeking to change a practical art into an applied science. Difficulties, of course, have been found all along the way, but experiment in medicine is for ever inevitable.

As a result of experiment in medicine we are, happily, gradually replacing anatomy by physiology, and if disease is, in many respects, merely altered function, then we are about to create a science, new to the human race, of comparative function in health and in disease. But experiment has done even more for us than that. It has strengthened the arm of medicine, and it has made the tests more severe for the acceptance of evidence which has been derived by the methods of observation.

Medicine depends, of course, not only for its present stability but also for its future advance, upon a large number of ancillary sciences. Those sciences are to be studied in the new building. The effect, therefore, on medicine will be considerable, but it is hoped something better even than that will come out of the work done in this institution, and similar institutions; that is, to create in the minds of the leaders of the profession what Sir Walter Morley Fletcher would call "The Religion of Research". Lord Moynihan said he hoped that the date would not be far distant when those who are to serve upon the teaching staffs of hospitals throughout Great Britain will be permeated by "The Religion of Research", and in time to come all members of the teaching staffs will themselves have undergone, in institutions similar to this, a discipline of research.

In concluding, Lord Moynihan said that by his constant thought Dr. Wellcome has done as much as any man has ever done in Great Britain to make it possible to advance both the science and the art of medicine.

By placing the Museum of Medical Science, including tropical medicine and hygiene, and the Historical Medical Museum under one roof, there is no doubt that in London there will be a combination which will be unequalled in the world.

The associated Physiological Research Laboratories will remain at Langley Court, Beckenham, and the Field Entomological Laboratory at Claremont, Esher.

Plant Breeding in Germany.

THE acceptance by Dr. Baur of the invitation of the Royal Horticultural Society to give the Masters Lectures in 1931 has resulted in the publication, in the *Journal of the Horticultural Society*, vol. 56, Part II, of two lectures which contain, in the first place, a most effective short statement of the present position of evolution, and in the second, a very interesting summary of the work in plant breeding that is being carried out, under Dr. Baur's direction, in the Kaiser Wilhelm Institut für Züchtungsforschung at Müncheberg.

Dr. Baur concludes that the experimental study of genetics has shown clearly that "inheritance of acquired characters in the sense of Lamarck does *not* exist". He argues that the main cause of what Darwin called hereditary variation is the combination of characters provided for by biparental inheritance, but differs from Lotsy because he considers that such variations are too limited to supply the needs of progressive evolution. Continued breeding of *Antirrhinum* has led him to the conclusion that the frequency of mutation is no less than 1·3–7 per cent, though such mutations are mainly recessive and therefore only distinguished on extensive and continued breeding trials. Most of these mutations are small, and a striking mutation is usually associated with loss of vitality. Dr. Baur concludes that through the selection of small mutations the differentiation of species out of parent species can be explained, and that wider differences may gradually arise because two such new forms, as they become separated by an increasing number of such 'small-point mutations', tend also to become infertile to one another.

Dr. Baur's account of the work of the Kaiser Wilhelm Institute is full of interest. The extensive breeding work, coupled with patient testing, which permits the isolation of a lupin free from poisonous alkaloids, after a million and a half plants have been examined, is a striking example of selection work. The recombination of Mendelian characters is carried out on normal lines, but on an extensive scale, with wheats, grapes, etc.; whilst new experiments are proceeding with attempts to induce variations artificially by chemical methods, as has been done so successfully in recent years by X-rays.

University and Educational Intelligence.

CAMBRIDGE.—The Vice-Chancellor has received a letter from the Trustees of the British Museum offering the sum of £2000 for the use of the Scott Polar Research Institute. This sum represents the greater part of the balance remaining of the sum which was subscribed to meet the cost of publishing the scientific results of Capt. Scott's *Terra Nova* expedition.

LONDON.—The title of professor has been conferred on the following: Mr. F. W. Twort (bacteriology), in respect of the post held by him at the Brown Animal Sanatory Institution; Dr. H. A. Harris (clinical anatomy), in respect of the posts held by him at University College and University College Hospital Medical School; Dr. F. A. P. Aveling (psychology), in respect of the post held by him at King's College

The title of reader in eugenics has been conferred on Miss E. M. Elderton, in respect of the post held by her at University College.

OXFORD.—On Nov. 17, Congregation passed a decree recording the grateful thanks of the University to Prof. J. Mark Baldwin, for a gift of £1000 for the capital endowment of the Edward Bagnall Poulton Fund, established for the encouragement of research in the subject of evolution. This fund has already been of much service in assisting work of the kind indicated.

At the same meeting of Congregation the thanks of the University were accorded to the Royal Astronomical Society for a generous gift to the Lewis Evans Collection of a set of more than fifty astronomical and mathematical instruments.

SHEFFIELD.—Prof. J. H. Andrew, professor of metallurgy at the Royal Technical College, Glasgow, has been appointed to the chair of metallurgy in the University in succession to Prof. C. H. Desch, who has been appointed superintendent of the Department of Metallurgy at the National Physical Laboratory.

ON Nov. 29 the Cinema Hall, which is maintained by the Empire Marketing Board at the Imperial Institute, South Kensington, reopened with a series of cinematograph displays, many of which are travel films of geographical interest. In future an admission charge of one penny is being made for each session. Monthly programmes of the films and lectures may be obtained on the payment of two shillings, being subscription for one year.

THE following scholarships will be offered by the Institution of Naval Architects Scholarships for competition in 1932: Naval architecture, Martell scholarship (£130 a year for 3 years); Denny scholarship (£75 a year for 4 years): Marine engineering, Parsons scholarship (£150 a year for 3 years); Denny scholarship (£75 a year for 4 years). The Denny scholarships are open to boys less than nineteen years of age from public or secondary schools who have not yet begun their apprenticeship, and are tenable at the University of Glasgow. The remaining scholarships are open to apprentices less than twenty-three years of age, and are tenable at the Royal Naval College, Greenwich, the University of Glasgow, Armstrong College (University of Durham), the University of Liverpool, and the City and Guilds (Engineering) College, London. Particulars may be obtained from the Secretary of the Institution of Naval Architects, 2 Adam Street, Adelphi, London, W.C.2.

Birthdays and Research Centres.

Dec. 6, 1858.—Prof. Hans Schinz, professor of systematic botany, formerly director of the Botanical Gardens and Museums of the University of Zurich.

At present I am engaged on the fifth edition of the "Flora of Switzerland", and on a flora of South West Africa, and I am also working on the Swiss Myxomycetes.

Dec. 7, 1855.—Prof. Henry Louis, consulting mining and metallurgical engineer, and emeritus professor of mining in Armstrong College, University of Durham.

Since my retirement from active work in the Armstrong College, University of Durham, my opportunities for engaging in actual researches have been somewhat limited. I am, however, continuing to take a keen interest, though now more in an advisory capacity, in researches bearing upon the subjects with which my work has been principally identified. One of the most important of these is probably the work that is being carried out by the Support of Workings Committee of the North of England Institute of Mining and Mechanical Engineers, of which I am secretary. Whilst the direct object of this Committee is a study of the conditions producing falls of ground in collieries, which are to-day the most serious source of mine accidents, its operations necessarily throw much light upon other important points, such as surface subsidence, the subsidence of the immediate roof of colliery workings, and the best form of support to be employed in such workings. I need scarcely say that this last aspect of the question is very closely connected with my metallurgical work, because it is becoming more and more evident that the replacement of timber by steel is playing an increasingly important part in the solution of this problem.

I am, of course, able to give a certain amount of time to reporting upon, and the valuation of, mineral deposits. Necessarily, much of this work, although involving a good deal of research, and not infrequently geological research of a tolerably high order of difficulty, is confidential, and must always remain unpublished. I have, however, in the press, a book on "Mineral Deposits" which will, I hope, embody the results of some personal observations. From the very nature of the work these observations must, of course, be somewhat out of date when published, but I hope that they may, nevertheless, be found of value.

Dec. 9, 1855.—Dr. F. A. Dixey, F.R.S., Hon. Fellow, late subwarden and bursar of Wadham College, Oxford.

I am, at present, examining the evolutionary relationships of various lepidopterous groups, as disclosed by the study of their structural characters; together with the phenomena of sexual and seasonal polymorphism and of mimicry in various forms, exhibited within the same groups.

Observations in the field on all bionomic details in the life of insects, in relation with their environment, whether organic or inorganic, are worthy of attention. Special consideration should be given to their means of protection against the attacks of predaceous organisms; the evidence of absolute or relative immunity conferred by their own defensive qualities; and the various influences which may affect the vigour of the assaults made upon them by their enemies. These interactions are all important from the evolutionary point of view, and the value of many of them can only be appraised by direct observation in the field, prompted by work done in the laboratory and museum.

Dec. 10, 1855.—Mr. H. N. Ridley, C.M.G., F.R.S., former Director of Gardens and Forests, Straits Settlements.

I am now turning my attention specially to the geographical distribution of plants and animals in various regions of the globe, with the view of showing the relationship of the present constituents of the floras and faunas of different countries to the previous geological history, and especially to the former distribution of land and water. Though the accounts of the floras of various regions have been extensively compiled geographically, so that comparisons may readily be made in most areas, this has been seldom the case in the matter of faunas, which have not often been treated geographically, and this would be most desirable. I am also continuing my researches into the flora of Borneo and the Malay islands.

Dec. 10, 1878.—Dr. W. K. Spencer, F.R.S., H.M. Inspector of Schools.

As my time for research has been limited, it has been necessary to confine myself to the palæontology of a small group of animals, the starfish and brittle starfish. The advantages of work upon a small group with which one can become well acquainted are now becoming evident.

The evidence of evolution afforded by the group shows that recent starfish are only remnants of an originally very diverse Palæozoic fauna, and that the lines which are able to initiate new inventions leading to greater command over environment are those which survive. I hope shortly to put forward a new classification of starfish based on observations of progressive evolution.

The distribution of Palæozoic starfish shows correspondence with that of other Palæozoic fauna, leading to conclusions regarding the currents of these older seas and the land boundaries. The form and ornament of isolated ossicles of Chalk starfish form a valuable accessory in zonal determination. The many groups of fossil animals and plants afford abundant opportunity to the non-professional scientific worker willing to concentrate on a small field.

Dec. 11, 1860.—Dr. Leonard Huxley, editor of the *Cornhill Magazine*.

Tuberculosis, yellowjack, malaria, typhus—these are a few names to remind us that science has sent her spies out against the great and terrible enemies ambushed along the path of life, and that her workers follow in battalions to consolidate the victories of knowledge. Great are the material gains, great, too, the relief of mind. The formless dragons of the dark are stripped of half their terrors. These are great and imposing victories: others no less great and imposing are on the horizon. But meantime there are certain elusive and disabling plagues, so common as to be vulgar, so repulsive, when not actually dangerous, as to earn more contempt than commiseration, so universal as to produce vast cumulative loss. What honour would not the long-suffering multitude accord to their deliverer from that 'horrid cold', that 'vile 'flu', to which they are so fatalistically accustomed to-day?

Dec. 12, 1855.—Mr. A. W. Clayden, formerly principal of University College, Exeter.

I am chiefly interested in the observation of cloud forms and their relation to weather.

If observations on the variations of the lapse rate, similar to those carried on at Duxford and elsewhere, could be made near the western seaboards of the British Isles, say Penzance and southern Ireland, the results would be interesting and might very well be important.

An interesting point which does not appear to have been much studied is the condensation of water vapour at low temperatures. Rime sometimes takes one dominant form, sometimes another. The crystals in one shower of fine snow are frequently of one type, while those of another shower show quite a different figure.

Dec. 12, 1866.—Prof. E. W. MacBride, F.R.S., professor of zoology in the Imperial College of Science and Technology, South Kensington, London.

The following problems are being investigated under my supervision:

(1) An attempt to repeat the experiments of Metalnikoff, which indicate the inheritability of acquired immunity.

(2) An attempt to repeat Kammerer's experiments on *Salamandra maculosa*, which indicate the responsiveness of its skin-colour to the background.

(3) An attempt to repeat Kammerer's experiments on *Alytes*, indicating the re-adaptation of this terrestrial type to aquatic life.

(4) An investigation by experimental methods of the late stages in the development of echinoderm larvæ. During these stages the possibility of evolving 'suppressed complexes' is indicated.

(5) An investigation into the action of various reagents on the eggs of the frog in producing abnormalities in late larval development.

Societies and Academies.

London.

Mineralogical Society, Nov. 4 (Anniversary Meeting).—**F. C. Phillips**: On crystals of brookite tabular parallel to the basal plane. Small yellow-brown rectangular plates in heavy residues from Middle Jurassic sandstones of N.E. Yorkshire are shown by optical and X-ray examination to be brookite of normal optic orientation but unusual crystallographic habit, being tabular parallel to the basal plane. They are associated in the residues with brookite of normal habit, abundant anatase, and rutile.—**T. Ito** and **T. Shiga**: On scorodite from Kiura Mine, Bungo, Kiushiu, Japan. The mineral occurs as small dark-brown and green crystals associated with vivianite, fluorite, and quartz in druses in veins of arsenopyrite intruded into limestone. Chemical analysis on carefully selected material gives a result consistent with the formula $FeAsO_4 . 2H_2O$. Forms present are (001), (100), (011), (120), (111), (201), (211), and (322). The crystals are orthorhombic with $a : b : c = 0·865 : 1 : 0·972$. The habit is pyramidal equidimensional. The 111 faces show abundant vicinal faces belonging to two principal zones $\{01\bar{1}\}$ and $\{10\bar{1}\}$.—**W. Campbell Smith**: On a new meteoric stone from Suwahib, Arabia. The stone was found in 1930 on the sand near Buwah, in Suwahib, by one of the Arabs accompanying Mr. Bertram Thomas on his journey across the Rub' al Khali. As found, it weighed just over 238½ gm. It is coated with limonite and shows no definite crust. It is a black chondrite belonging to Prior's Cronstad type, with more than ten per cent of nickel-iron. The density is 3·52.—**Edward S. Simpson** and **D. G. Murray**: A new siderolite from Bencubbin, Western Australia. A mass weighing 119·5 lb. (54 kgm.) was found in 1930 near Bencubbin, about 150 miles north-east of Perth. It consists of a skeleton of nickel-iron (68·8 per cent) with enclosed crystals up to 1 cm. across, of greyish-white enstatite (13·5 per cent) and dark olivine (12·5 per cent). In the metallic portion Fe : Ni = 15 : 1. The meteorite is classed as a mesosiderite with an unusually high proportion of nickel-iron.—**A. R. Alderman**: The meteorite craters at Henbury, Central Australia. The locality is known locally as the Double Punch-bowl, from the two largest adjoining craters. It is situated seven miles west-south-west of Henbury cattle station on the dry Finke river, and about fifty miles south of the McDonnell Ranges in the very centre of Australia. Within an area of 500 yd. by 500 yd. thirteen craters were mapped. The largest is oval in outline, measuring 220 yd. by 120 yd. across, and with a depth of 50-60 ft. The other craters are roughly circular, with diameters ranging from 10 yd. to 80 yd. The walls consist of powdered rock and shattered blocks of Ordovician sandstone and slaty rock. Owing to the craters acting as collecting pans for rain-water in this arid region, the spots are prominently marked by the growth of mulga trees, acacias, and coarse grass. Scattered around the craters are numerous pieces of metallic iron, usually angular in shape, and ranging from a fraction of an ounce to 52½ lb. in weight. In one area of 6 ft. by 6 ft. more than a hundred fragments were collected. Only two masses (one of 13 lb.) were found within the crater walls; and in one of the smaller craters a bore-hole to a depth of 8 ft. through fine silt down to coarse rock fragments yielded no mass of iron. Fragments of iron rust are also abundant; and some glassy material, suggesting fusion of the country rock, was found. These craters, which are very similar, were evidently formed by the impact of a shower of meteoric irons at some remote period.

Geological Society, Nov. 13.—**E. J. Wayland**: The Katwe crater-lake, Uganda. Lake Katwe occupies the bottom of an explosion crater of the caldera type and is the source and centre of a flourishing native-managed salt industry. Lake Edward oscillates in accordance with the sunspot cycle, while Lake Katwe does not. While the level of the former is above the water-table, that of the latter is determined and maintained by it. Although the volcanic vent passes through the saturation zone, its upper parts are more or less completely sealed off from the surrounding ground-water by deposits of the less soluble salts thrown out of solution at successively lower levels as temperature decreased with time. Within the tube so formed, aqueous circulation is produced by the temperature gradient, and the most soluble of the salts, derived at depth from decomposing alkali lavas, are thereby brought to the surface and, as a consequence of solar evaporation, are deposited in the shallow lake.—**Arthur Holmes** and **Henry Francis Harwood**: Petrology of the volcanic fields east and south-east of Ruwenzori, Uganda. Towards the close of the period in which the Kaiso lacustrine beds were deposited, volcanic activity broke out along a series of belts extending north and south of Fort Portal and north and south of the Kazinga Channel. The first phase (Lower to Middle Pleistocene) is represented by sub-aqueous tuffs. Post-Kaiso rifting movements followed, and were succeeded in turn by a second phase of vulcanism, in which explosion vents were blown through the rift-valley floor, the bordering scarps, and the adjoining plateau. The rocks of this stage include tuffs and agglomerates, ejected blocks, and volcanic bombs. Throughout the area the earlier tuffs appear to represent melilite-basalts. The tuffs are followed by others having compositions transitional towards that of leucitite. The later cognate ejected blocks include melanocratic varieties of potash-nephelinite and leucitite. Accompanying them are bombs of leucitite and olivine-leucitite, some of the latter being sufficiently rich in olivine to be regarded as a volcanic equivalent of kimberlite. The volcanic belts together constitute a co-magmatic region of a highly individualised kind.

PARIS.

Academy of Sciences, Oct. 26.—**P. Villard**: The reduction of soda. Caustic soda is reduced to sodium by heating with manganese (or ferromanganese) at 700° C. Some potassium was also obtained from caustic potash. The manganese can be replaced by chromium (800° C.), iron (750° C.), cobalt, nickel (600°-750° C.), or tungsten. No reduction was observed with zinc.—**Léon Guillet, Albert Roux**, and **Jean Cournot**: New remarks concerning the influence of occluded gases on the mechanical properties of metallurgical products. The authors have repeated the experiments of Guichard, Claussman, Billon, and Lanthony and arrive at a different conclusion. They consider it is impossible to agree with the statement that the hardness of electrolytic iron is completely independent of the proportion of hydrogen present in the metal.—**P. Vincensini**: Isotropic congruences and minimum surfaces.—**Gaston Julia**: The trend of iterated series in the neighbourhood of boundaries of convergence.—**Maurice Gevrey**: The determination of the integrals of systems of linear partial differential equations of the elliptic type.—**Arnaud Denjoy**: The Riemann definition of the Lebesque integral.—**J. Le Roux**: The conditions of application of the principle of relativity.—**J. Rossignol**: The problem concerning cylindrical vortices of finite section.—**Henri Quillery**: A method for securing fixed ratio of air to petrol in carburettors.—**Th. Got**: The calculation of the critical velocities of rotating shafts of constant section and non-negligible mass, carrying perfectly centred thin discs.—**D. Barbier**: Remarks on the dynamical parallaxes of double stars.—**J. Dufay**: The spectrum of the eclipsed moon. The moon, when passing through the earth's shadow, is illuminated only by the rays refracted by the earth's atmosphere, and hence the study of its spectrum allows the observation on an unusual scale of the effects produced by diffusion and selective absorption of our atmosphere. Photographs taken during the eclipse of Sept. 26 showed the solar line $C(H\alpha)$, two oxygen bands (one very strong), and others not identified.—**René Gindre**: The photometric study of the eclipse of the moon, Sept. 26, 1931.—**A. Danjon**: Photometric and colorimetric study of the total eclipse of the moon of Sept. 26, 1931.—**Ernest Esclangon**: Remarks on the preceding note.—**L. Eblé** and **E. Salles**: Some measurements of gravity in the Paris region.—**Dalloni**: A scientific expedition to Tibesti.—**B. Décaux** and **Ph. Le Corbeiller**: A self-maintained electrical system utilising a neon tube. If a battery, a neon tube, and a condenser are mounted in series, flashes in the tube separated by periods of longer duration are noted. As an example, with an e.m.f. of 200 volts, a condenser of 6 microfarads showing a leak resistance of 20 megohms, a neon lamp of the night-light type gives flashes every 20 seconds. A theoretical explanation is given.—**Edgar Pierre Tawil**: The origin of the third fundamental frequency of oscillating piezo-electric quartz.—**G. Bruhat** and **J. Thouvenin**: The realisation of a quarter wave plate for the ultra-violet with the aid of oblique quartz.—**R. de Mallemann**: Molecular dissymmetry.—**Pierre Lambert** and **Ion Agarbiceanu**: The magnetic change of the absorption lines of nitrogen peroxide.—**H. Forestier** and **M. Galand**: The study of beryllium ferrite and the ferric oxide arising from its decomposition. The variation of the magnetic properties with temperature and the X-ray study (Debye-Scherrer method) lead to the conclusion that the mechanism of formation of the ferric oxide attracted by a magnet, starting with beryllium ferrite, is the same as that of Malaguti's oxide, formed by the dehydration of certain natural and artificial oxides of iron. The atom of beryllium in the ferrite has the same function as that of the molecule of hydrogen in the hydrate $Fe_2O_3 . H_2O$.—**Ch. Marie** and **N. Marinesco**: The volume contraction produced by the hydration of proteins. The contraction of volume produced by the solution of gelatin proves that strong compressions exist between the dispersing medium and the particles of the dissolved body. The variation of this contraction with the hydrogen ion concentration allows the swelling and viscosity of the same colloid to be interpreted with regard to its isoelectric point.—**P. Mougnaud**: The note of MM. Carrière and Janssens relating to the estimation of fluorine. The author still considers the precipitation of calcium fluoride in ammoniacal solution is too inaccurate for practical use.—**Jacques Maroger**: The reconstitution of the painting technique of Jean Van Eyck. Details are given of the preparation of an oil medium which can be regarded as a reconstitution of the medium used before the beginning of the nineteenth century.—**Jean Chevrier**: Researches on the electrical field of the air at Djesireh.—**E. Chemin**: The protein crystals in some marine species of *Cladophora*.—**A. Famin**: The action of temperature on the nucleus and karyokinesis in *Vicia faba*.—**Marc Bridel** and **Mlle. A. Kramer**: The constitution of asebotoside (asebotine): its identity with phlorizoside (phlorizine). The comparative study of the glucoside extracted from the leaves of *Kalmia latifolia* (asebotoside) and the glucoside extracted from the bark of apple and pear trees (phlorizoside) has proved the complete identity of these two substances. It follows that the name asebotoside should disappear from chemical literature.—**Pierre Chouard**: Analogies between the development of the young plant and the annual push of the leaves in the Liliaceæ.—**A. Vandel**: The existence of two species of *Spiloniscus*, hitherto confused, and their reciprocal relations.—**J. André Thomas**: The action of sea water, in which carotene has remained, on the experimental development of the sea urchin *Paracentrotus lividus*. The carotene employed, although theoretically insoluble in water, communicates properties to sea water affecting the experimental development of the egg of the sea urchin.

CRACOW.

Polish Academy of Arts and Sciences, Oct. 5.—**Ladislas Natanson**: General propositions connected with Fermat's principle and certain other associated theorems.—**St. Rafalowski**: The Raman bands in water. In the case of a solution of hydrochloric acid it has been found that the extreme components of a band weaken as the concentration in acid increases, whilst the middle component widens. This is not in agreement with the statement of Rao (see also NATURE, 128, 546, Sept. 26, 1931).—**K. Dziewonski** and **Zb. Reicher**: Studies on 2-benzylfluorene.—**A. Gawel**: The granites of the Carpathian flysch of Krosno in the neighbourhood of Sanok.—**J. Kuhl**: The formation of kaolin and of alunites in the eastern part of the Ste. Croix mountains (Montagnes du Poivre) in the neighbourhood of Sandomierz.—**E. Malinowski** and **Mlle. A. Smólska**: The mosaic strain of *Petunia violacea*.

Diary of Societies.

FRIDAY, December 4.

Royal Society of Medicine (Otology Section), at 10.30 a.m.
Institution of Water Engineers (at Institution of Civil Engineers), at 10.30 a.m.
Royal Society of Arts (Indian Section), at 4.30.—Sir George Birdwood Memorial Lecture.
Royal Society of Medicine (Laryngology Section), at 5.
Physical Society (at Imperial College of Science and Technology), at 5.
British Psychological Society (Æsthetics Section) (Annual Meeting) (at Bedford College), at 5.30.
Society of Chemical Industry (Liverpool Section) (at Liverpool University), at 6.
Institution of Electrical Engineers (Meter and Instrument Section), at 7.
Society of Chemical Industry (Manchester Section) (at Engineers' Club, Manchester), at 7.
Royal Photographic Society of Great Britain, at 7.
Junior Institution of Engineers (at Royal Society of Arts), at 7.30.—Dr. S. L. Pearce: Presidential Address.
Geologists' Association (at University College), at 7.30.
Railway Club (at 57 Fetter Lane), at 7.30.
Institute of British Foundrymen (Middlesbrough Branch) (at Cleveland Scientific and Technical Institute, Middlesbrough), at 7.45.
Royal Society of Medicine (Anæsthetics Section), at 8.30.
Royal Institution of Great Britain, at 9.

SATURDAY, December 5.

Royal Institution of Great Britain, at 3.
Gilbert White Fellowship (at 6 Queen Square, W.C.1), at 3.
Institute of British Foundrymen (Lancashire Branch) (at College of Technology, Manchester), at 4.

MONDAY, December 7.

Cambridge Philosophical Society (in Cavendish Laboratory, Cambridge), at 4.30.
Royal Society of Edinburgh, at 4.30.
Royal Geographical Society, at 5.
Royal Institution of Great Britain, at 5.—General Meeting.
Society of Engineers (at Geological Society), at 6.
Institution of Electrical Engineers (Informal Meeting), at 7.
Institution of Electrical Engineers (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.
Institution of Electrical Engineers (South Midland Centre) (at Birmingham University), at 7.
Institution of Rubber Industry (at Engineers' Club, Manchester), at 7.
British Kinematograph Society (at Gaumont Theatre, Wardour Street), at 7.45.
Royal Society of Arts, at 8.
Society of Chemical Industry (London Section) (at Chemical Society), at 8.

TUESDAY, December 8.

Manchester University Chemical Society (at Manchester University), at 5.
Royal Institution of Great Britain, at 5.15.
Institution of Petroleum Technologists (at Royal Society of Arts), at 5.30.
Institute of Marine Engineers, at 6.
Institute of Metals (Swansea Local Section) (at Y.M.C.A., Swansea), at 6.15.
London Natural History Society (Ramblers' Section) (at London School of Hygiene and Tropical Medicine), at 6.30.
Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.
Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester), at 7.
Institution of Heating and Ventilating Engineers (Associate Members' and Graduates' Section—Manchester and District Branch) (at Engineers' Club, Manchester), at 7.
Royal Photographic Society of Great Britain, at 7.
Institution of Automobile Engineers (Coventry Centre) (at King's Head Hotel), at 7.30.
Institution of Electrical Engineers (Scottish Centre) (at 39 Elmbank Crescent, Glasgow), at 7.30.
Institute of Metals (North-East Coast Local Section) (jointly with Society of Chemical Industry) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.
Institution of Welding Engineers (North-Western Branch) (at College of Technology, Manchester), at 7.30.
Royal Anthropological Institute, at 8.30.
Royal Society of Medicine (Psychiatry Section), at 8.30.
Pharmaceutical Society of Great Britain, at 8.30.
Institution of Electrical Engineers (East Midland Sub-Centre) (jointly with Institute of Fuel) (at University College, Nottingham).

WEDNESDAY, December 9.

Institution of Engineering Inspection (at Royal Society of Arts), at 5.30.
Institution of Civil Engineers (Informal Meeting), at 6.
North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.
Institution of Electrical Engineers (Hampshire Sub-Centre) (at Municipal College, Portsmouth), at 7.30.
Royal Society of Arts, at 8.30.—Sir Henry Maybury: Roads and Road Transport (Trueman Wood Lecture).

THURSDAY, December 10.

Royal Society, at 4.30.
London Mathematical Society (at Royal Astronomical Society), at 5.
Royal College of Surgeons of England, at 5.—Col. W. P. MacArthur: The Surgeon and Old-time Plague (Thomas Vicary Lecture).
Royal Aeronautical Society (at Royal Society of Arts), at 6.30.
Institute of Marine Engineers (Junior Section), at 7.
Royal Photographic Society of Great Britain, at 7.
Institute of Metals (Birmingham Local Section) (at Chamber of Commerce, Birmingham), at 7.
Institute of Chemistry (at Derby Technical College), at 7.15.
Institute of Metals (London Local Section) (jointly with Institute of British Foundrymen) (at 83 Pall Mall, S.W.1), at 7.30.
Society of Chemical Industry (Bristol Section) (jointly with Chemical Engineering Group) (at Bristol University), at 7.30.
Institution of Electrical Engineers (Dundee Sub-Centre) (at University College, Dundee), at 7.30.
Institution of Mechanical Engineers (Yorkshire Branch) (Annual General Meeting) (at Hotel Metropole, Leeds), at 7.30.
North-East Coast Institution of Engineers and Shipbuilders (Tees-Side Branch) (at Cleveland Scientific and Technical Institution, Middlesbrough) (jointly with Institution of Electrical Engineers—Tees-Side Sub-Centre), at 7.30.
Optical Society (at Imperial College of Science and Technology), at 7.30.
Institution of Welding Engineers (at Institution of Mechanical Engineers), at 7.45.
Royal Society of Tropical Medicine and Hygiene (at London School of Hygiene and Tropical Medicine), at 8.15.
Royal Geographical Society, at 8.30.—H. G. Watkins: The British Expedition to Greenland.
Diesel Engine Users' Association (at Caxton Hall).
Institution of Mechanical Engineers (Glasgow Centre) (at Glasgow).—Ll. B. Atkinson: Thomas Hawksley Lecture.

FRIDAY, December 11.

Andersonian Chemical Society (at Royal Technical College, Glasgow), at 3.15.
Biochemical Society (at London School of Hygiene and Tropical Medicine), at 3.30.

Royal Astronomical Society, at 5.—Prof. Freundlich: On the Gravitational Deflection of Light (Total Solar Eclipse, 1929, May 9).

Royal Geographical Society, at 5.

Royal Society of Medicine (Ophthalmology Section) (at Royal Eye Hospital, St. George's Circus), at 5.

Malacological Society of London (at Linnean Society), at 6.

Institution of Chemical Engineers (at Chemical Society), at 6.

Institution of Mechanical Engineers, at 6.

North-East Coast Institution of Engineers and Shipbuilders (at Mining Institute, Newcastle-upon-Tyne), at 6.

Society of Dyers and Colourists (jointly with Manchester Literary and Philosophical Society—Chemistry Section) (at 36 George Street, Manchester), at 7.

Institution of Electrical Engineers (London Students' Section), at 7.

Geologists' Association (North-East Lancashire Group) (at Blackburn Technical College), at 7.

Illuminating Engineering Society (at Royal Society of Arts), at 7.—Sir Francis Goodenough: Presidential Address.

West of Scotland Iron and Steel Institute (at Royal Technical College, Glasgow), at 7.15.

Society of Chemical Engineers (South Wales Section) (at Thomas' Café, Swansea), at 7.30.

Junior Institution of Engineers, at 7.30.

Royal Institution of Great Britain, at 9.

Oil and Colour Chemists' Association (Manchester Section) (at College of Technology, Manchester).

SATURDAY, December 12.

Geologists' Association (Demonstration at Natural History Museum), at 2.30.

North of England Institute of Mining and Metallurgical Engineers (at Newcastle-upon-Tyne), at 2.30.

Royal Institution of Great Britain, at 3.

Public Lectures.

SATURDAY, December 5.

Mathematical Association (London Branch) (at Bedford College for Women), at 3.—J. W. N. Sullivan: Mathematics and Culture (Presidential Address).

Horniman Museum (Forest Hill), at 3.30.—Prof. J. R. Ainsworth-Davis: Insect Pests and their Enemies.

MONDAY, December 7.

University of Leeds, at 5.15.—Prof. G. Barger: Ergot and Ergotism.

TUESDAY, December 8.

Imperial Institute, at 2.15.—Major H. Lockwood Stevens: Unknown Nepal.

WEDNESDAY, December 9.

Imperial Institute, at 2.15.—Miss Margaret Green: Our Voluntary Hospitals and the Nurse's Vacation.

Royal Institute of Public Health, at 4.—Prof. E. L. Collis: The Health of the Industrial Worker.

School of Oriental Studies, at 5.15.—A. W. G. Malcolm: Medicine in Africa.

Belfast Museum and Art Gallery, at 8.—E. E. Evans: The Beginnings of our Civilisation.

THURSDAY, December 10.

Imperial Institute, at 2.15.—Comdr. the Hon. S. Hay: A Midshipman's Experiences in the Pacific.

Science Museum (South Kensington) (in connexion with Exhibition of Modern Glasses), at 4.45.—E. A. Coad-Pryor: Glass in the Foodstuffs Industry.

King's College, London (at 16 Russell Square, W.C.1), at 5.30.—S. P. Turin: Russian Imports and Exports.

Battersea Polytechnic, at 7.—Dr. H. Phillips: The Walden Invasion: the Mechanism of the Substitution of Groups in Saturated Organic Compounds.

SATURDAY, December 12.

Horniman Museum (Forest Hill), at 3.30.—Dr. W. G. Ivens: Negroid Peoples of the Pacific Islands.

Science and Agriculture in New Zealand.

SINCE Lord Bledisloe's appointment as Governor-General of New Zealand, he has taken every opportunity of emphasising the need for scientific work as the basis of development of the country's resources. He has the unusual advantage of combining administrative ability with agricultural knowledge and a high appreciation of the possibilities presented by scientific research, and he has the courage to express his convictions clearly and without ambiguity. Before leaving Great Britain, he had, as chairman of the Lawes Agricultural Trust, the committee which manages the Rothamsted Experimental Station, the opportunity of familiarising himself with the detailed working of a great agricultural experiment station, and as chairman of the Long Ashton Research Station Committee he had had similar experience of a fruit research station. He was therefore well equipped for his work. He has, of course, been fortunate in his field of action. In no part of the Empire is there a higher standard of intelligence and ability among agriculturists, pastoralists, and fruit growers than in New Zealand. Right from the outset, universities were founded and agricultural education fostered. Nowhere is a worker in agricultural science better received than in New Zealand.

It is no accident that, in a world of agricultural depression, New Zealand, although largely dependent on agriculture, is probably suffering less than any other country at the present time. The agricultural development of New Zealand reads almost like a romance: it has all occurred so rapidly, yet with such certainty. From 1840, when organised settlement began, until 1880, sheep ranching was the main occupation and wool the chief export. There had been an export of wheat after 1870, the result of Vogel's development policy, until the invention of refrigeration paved the way for the great dairy and lamb industries, which are now among the most remarkable and efficient agricultural industries in the world. The invention came from Australia ; in 1873, James Harrison had been awarded a gold medal at the Melbourne Exhibition for his method of freezing meat. But the method was not developed until 1879, and then it was not successful. The first satisfactory cargo of frozen mutton and lamb arrived at London from New Zealand in 1882 in a sailing ship fitted with refrigeration appliances ; ten years later steamers were introduced, and continuous improvements have since been made.

On the agricultural side also the industry has developed remarkably, and from 1921 onwards it has been the subject of a good deal of legislative control, for the New Zealand farmer has learned to combine freedom of action in producing with united action in grading and marketing, and in consequence he has been able to send to Great Britain large and regular supplies of uniform high quality, and so to secure an enviable position in our markets. He does this at a profit, in spite of his great distance from our markets and of having to pay wages much higher per man (though not per job) than are paid here. The exports are rapidly rising. In 1929 that of butter was valued at £13·2 millions, of cheese £7 millions, frozen meat (mutton and lamb) £9·9 millions; in all, more than £30 millions by refrigeration transport, as against £15 millions of wool—a truly remarkable progress.

The development of the dairy industry, however, was not simply a matter of transport: it is a triumph for the bacteriologist, who has reduced to an exact science the art of producing clean milk, good butter, and cheese true to type.

No better illustration of the advantage of science to a community could be desired. But New Zealand does not rest satisfied with past achievements; it is perpetually improving its scientific equipment. The Cawthron Research Institute at Nelson in South Island, founded by Thomas Cawthron, a Camberwell man; the Canterbury Agricultural College, also in South Island; and the Massey Agricultural College in North Island, are all vigorous institutions, the first two well established and already held in high esteem among the agricultural institutes of the world, the last named new, well equipped, and with possibilities of a great career of usefulness. On the opening of this institution, Lord Bledisloe gave an address in which he summarised in a masterly way the economic and technical problems facing the New Zealand farmer, indicating also the lines on which they could be solved. " Even the most impoverished countries of the world ", he said, " have found public expenditure upon scientific research and the scientific guidance of their farming population to be a sound and remunerative investment."

This is an undeniable truth, and it holds generally; it is not confined to the agricultural population. Of all departments of public life, those concerned with the fostering of scientific work can least be spared. In the present national emergency, agricultural scientific workers, like their colleagues in other branches, are prepared to help shoulder the burden, but they ask that the work shall not be allowed to suffer, for it is even more needed in days of trouble than in days of prosperity. Great Britain has a good organisation for agricultural research and education, and an enthusiastic body of workers who have gained the confidence of farmers by the proved value of the help they have been able to render to the industry. It has taken years of patient work to build up the organisation and to train the workers: once destroyed, it would take even longer years to rebuild, because of the lack of confidence. Happily, the indications are that those charged with the invidious and thankless task of making national expenditure fit national means are fully alive to the imperative need of keeping intact the scientific organisation of Great Britain.

Sidelights on the British Association.

Advancing Science: being Personal Reminiscences of the British Association in the Nineteenth Century. By Sir Oliver Lodge. Pp. 191. (London: Ernest Benn, Ltd., 1931.) 6*s*. net.

MAXWELL'S "Treatise on Electricity and Magnetism " was published in 1873. H. J. S. Smith was president of Section A of the British Association which met at Bradford that year, and in his presidential address referred thus to the work: " For electricity now, like astronomy of old, has placed before the mathematician an entirely new set of questions, requiring the creation of entirely new methods for their solution ". Among his hearers was Oliver Lodge, then an enthusiast, twenty-two years of age, attending his first British Association meeting, greatly impressed by the distinguished men present, who were taking an active part in the proceedings. Soon afterwards he conceived the idea, as he tells us in the interesting note contributed to the Maxwell commemoration volume,* of making the production and demonstration of the electromagnetic waves predicted by Maxwell the work of his life.

For the next twenty-five years or more Lodge was a regular and welcome attendant at British Association meetings, and we have now his personal reminiscences up to the end of the century. And most interesting they are to all who care to learn something of the development of science during that period, specially perhaps to one who, like the reviewer, attended many of the meetings and is reminded by this record of the sayings and doings of friends now passed away.

The book had its origin in a suggestion by Dr. Ferguson, secretary of the Physical Society, that Sir Oliver should record his notion of what the

---

* James Clerk Maxwell: a Commemoration Volume, 1831–1931. (Cambridge: At the University Press, 1931.) See NATURE, Oct. 10, p. 607.

British Association and the big men associated with it accomplished during the latter third of the nineteenth century; the headings of some of the sections are sufficient to illustrate its scope.

Commencing with a brief notice of Huxley, Tyndall, and Clerk Maxwell in the first chapter, we pass on to Crookes and radiant matter, and Fitzgerald on ether waves in the years 1879–83. Then comes an interesting account of the first Dominion meeting, at Montreal, under Lord Rayleigh's presidency, followed by Kelvin's vortex theory of the ether and the long discussions on the seat of the e.m.f. in a voltaic cell, 1885–87; the discovery of electric waves, Bath, 1888; the National Physical Laboratory with a section about the Red Lion Club; argon and the beginnings of wireless, 1892–1894, and finally the discovery of the electron, 1895–1900.

In his survey the author covers the whole range of subjects dealt with in Section A during thirty years, bringing back to the memory of many of his readers the salient points of discussions to which they listened and illustrating them by his own vivid recollections. Perhaps the most interesting pages are those in which he gives the history of electric waves and tells the story how he carried out the resolve made at Bradford in 1873.

Sir Oliver met Fitzgerald at Dublin in 1878 and was captivated at once by that most charming of men, a skilful physicist, a brilliant mathematician, and a daring thinker—witness his prediction in 1894 or '95 that the length of a yard stick might depend on its orientation; he had absorbed all that was involved in Maxwell's theory, and in 1880 laid before the British Association a paper on the possibility of originating wave disturbances in the ether by electromagnetic forces. At Southport in 1883 he calculated the energy lost per second by a circular ring carrying an alternating current and described a method of producing electromagnetic disturbances of comparatively short period; it was the method now used in wireless. But at the time the friends went no further. Four years later (1887) Lodge gave the Mann Lectures of the Society of Arts on protection from lightning, in which he directed attention to the importance of the self-induction of a lightning conductor leading to an alternating discharge. That same year, Hertz, at Carlsruhe, was investigating the " Outspreading of Electric Force ", as he called the waves coming from a circuit carrying a rapidly alternating current.

We heard of this in Cambridge early in 1888 and welcomed with enthusiasm this verification of the theory of our master. It is all in Maxwell, we said; no one had realised that by tuning the receiving circuit the tiny effects which we knew were there could be made visible. Fitzgerald was president of Section A that year (1888) at Bath and made a description of Hertz's work a main portion of his address. A paper by Lodge dealing with the propagation of waves along wires appeared in the *Phil. Mag.* for August 1888. In the years following, lectures were given and experiments shown to illustrate the Hertzian waves; reference may be made to one by Lodge at Oxford in 1894, in which he outlined the possibility of their extension to wireless telegraphy; in this work he was helped by Alexander Muirhead.

Two years later, at Liverpool, Sir William Preece, Chief Engineer to the Post Office, told Section A of Marconi's work, and wireless as we now know it, aided by Lodge's work on tuning, came into being. The discovery of the electron, announced at Dover by J. J. Thomson, in 1899, completes the story. Wireless had been held back by the need for a sufficiently sensitive receiver, and somewhat later (1904) Fleming showed that the stream of electrons from a hot cathode in an exhausted bulb constituted a much better detector than any coherer or crystal device.

Sir Oliver treats in a similar way, though not so fully, many of the other discussions and discoveries of those pregnant five-and-twenty years; for the story we must refer the reader to his reminiscences; and these are not all dry science. He tells of the spade work of a delegate who persuaded the Association to visit Southport—he does not mention his speech to the General Committee met to determine the next place of meeting. The Committee was getting a little bored by a delegate from Leicester, who spoke of the antiquity and history of his city, of its interests from the time of Simon de Montfort to the present day, ending with a lecture on the geology of the neighbourhood. The Southport delegate followed with the statement: Southport has no history; Southport has no antiquities; Southport has no geological formation, but it will give the Association a hearty North Country welcome; and he sat down. The Committee voted for Southport.

Again, at Dublin, our author found there the senior fellows spent much time telling comic tales. I once heard an elderly lady—this is not in Sir Oliver's book—ask one of the brilliant group mentioned: " Is that really true ? " to receive the reply, " Have you not yet learned, Mrs. M., that truth spoils stories ? "

The secretaries often had amusing experiences;

no doubt they still have; let me conclude with one of my own. It was in a cathedral city, and in discharge of my duty I had declined as politely as possible a paper on the ether scarcely suited for Section A. It was too theological. I went to the cathedral service on the Sunday of the meeting, when a venerable gentleman ascended the pulpit and from that secure position read to the assembled congregation the paper I had returned to him some few days earlier.

But it is not stories of this kind which give value to Sir Oliver's book. In a life of eighty years, he has made many of us his debtors; he has added to our debt by telling of advancing science during the last quarter of the nineteenth century in a manner which only he could achieve.

R. T. G.

Physics of the Earth.

Bulletin of the National Research Council. No. 77: *Physics of the Earth.* 1: *Volcanology.* By the Subsidiary Committee on Volcanology. Pp. viii+77. 75 cents. No. 78: *Physics of the Earth.* 2: *The Figure of the Earth.* A Collection of Short Papers, written by Leading Scientific Men in several branches of Geophysics, and treating of the Size and Shape of the Earth. Pp. v+286. 3.50 dollars. No. 79: *Physics of the Earth.* 3: *Meteorology.* Prepared under the auspices of the Subsidiary Committee on Meteorology. Pp. xi+289. 3.50 dollars. No. 80: *Physics of the Earth.* 4: *The Age of the Earth.* Pp. v+487. 4.50 dollars. (Washington, D.C.: National Academy of Sciences, 1931.)

THE books under review are the first four of a series of nine bulletins of the United States National Research Council, on various branches of geophysics, begun in 1926 under the stimulus of Prof. J. S. Ames. The preparation of each is in the hands of a very representative subcommittee.

The first, on volcanology, is in three sections, by Drs. K. Sapper, I. Friedlander, and T. A. Jaggar. It must be recognised, and the authors do recognise throughout, that physical volcanology has a considerable future, but no past and not much present. The first two chapters are mainly descriptive of the various forms of volcanic activity, with brief accounts of former attempts at explanation. The latter give the impression that most of them would have been better left buried. Jaggar's essay is what the subject needs; it is stimulating and full of ideas for future work. One may pick out for special mention his suggestion of the use of spectroscopic methods to determine the composition of the gases emitted, his explanation of the difference in level between the craters of Kilauea and Mauna Loa, and the following remark, in relation to volcanic rocks: "The real geological interest is quantity of commonest types. The laboratory interest is quality of uncommon types." Much use is made of the work of Day and Shepherd on the temperatures of lavas; but one wishes that Day himself had contributed more than a preface.

The second volume, nominally on "The Figure of the Earth", covers the figure of the earth, isostasy, tides, and the variation of latitude. There are sixteen chapters, by various authors; some deal with observational technique, some with methods of computation, while others are purely theoretical. Dr. A. T. Doodson contributes a comprehensive semi-popular account of tidal theory, explaining in general terms the amphidromic points—those places in open seas and oceans around which the tidal wave appears to circulate—and brings out the interesting point that the tide in the Atlantic as a whole is largely a matter of resonance. Dr. H. A. Marmer's account of mean sea-level makes the theorist marvel at the observational skill of the survey that has shown that the mean level of the sea is not perfectly flat, but shows variations of a few inches as between places hundreds of miles apart. Dr. W. D. Lambert's chapters on the bodily tides and on tidal friction constitute an excellent historical and critical summary of the present state of these subjects.

Dr. W. Bowie gives a historical account of the theory of isostasy, and gives proper credit to Airy as the real originator of the idea. But Prof. H. Fielding Reed, in the next chapter, seems to go completely astray in deciding for Pratt's theory against Airy's on geological evidence. He admits folding as the cause of mountain structure, while Pratt made no allowance whatever for folding. Granted the existence of several distinct layers in the crust, each lighter than the one below it, which is demanded both by geological evidence and by the modern study of near earthquakes, any crustal shortening such as gives rise to folding means an extra thickness of light matter on top. If then there is no corresponding excess of gravity, this can be due only to a deficiency of the heavier matter below; that is, to a depression of the base of the lighter layers. This is precisely Airy's theory. Prof. Reed gives evidence that in some cases the folding took place before the uplift, and argues that this fact is in favour of Pratt's theory and destructive of Airy's. This is not the case. Granted compression without uplift, the result would be a replacement of heavy matter by an equal *volume* of light matter, and therefore a deficiency of gravity. If then subsequent uplift took place by Pratt's mechanism—vertical expansion—the mass per unit area would remain as it was, and the deficiency of gravity would persist. This is in contradiction to the observed fact that gravity in mountainous regions is sensibly normal. Prof. Reed's theory errs in the opposite direction from the old idea of the mountains as excess loads.

Dr. Lambert contributes a further article, largely historical, on the theory and measurement of the figure of the earth. It is pleasant to see an account of Stokes's formula for the determination of the deviation of the geoid from the spheroid, given the variation of gravity over the surface; as Lambert says, eighty years after Stokes enunciated his theorem, observations of gravity are becoming sufficiently numerous to make its application possible.

Dr. Swick gives an account of methods of measuring gravity (including that of Meinesz). Other geodetic articles are contributed by D. C. Barton, D. L. Parkhurst, H. G. Avers, and C. V. Hodgson, and Dutton's classical paper is reprinted.

The final section deals with the variation of latitude, Lambert again being the principal author. He discusses incidentally Darwin's paper on the secular shifting of the pole, and shows that by a mathematical oversight Darwin was more favourable to this hypothesis than the circumstances warranted.

The third volume deals with meteorology, both from the observational and theoretical points of view. It is very full, both in description and in the accounts of the thermodynamics and dynamics of the atmosphere. But we notice with wonder that what we are used to call the eddy viscosity is called the Austausch coefficient, that this is said to be the usual English practice, and that Prof. G. I. Taylor is not mentioned in relation to it. Nevertheless, the amount of material is remarkable, considering the size of the volume.

The appearance and arrangement of the books are attractive, though there are rather too many misprints.

The first three volumes are in the nature of critical summaries of existing knowledge. The fourth, however, is a full and detailed account. The greatest part of it, nearly three-quarters, is by Prof. Arthur Holmes, and deals with the measures of geological time based on radioactive disintegration. A serious attempt has been made to discuss all the relevant analyses, a formidable mass of material. Holmes begins at the beginning with a general account of radioactivity; he adopts the view that the lead isotope of atomic weight 207 is the final product of the actinium series, derived ultimately from an isotope of uranium, probably of atomic weight 235. Rutherford's interesting estimate of a maximum age of the earth from the amounts of the elements in the actinium series is given fully. Pleochroic halos occupy a chapter. In the discussion of lead/uranium ratios the constants adopted are altered slightly from those previously recommended by Holmes and Lawson, and the whole of the data have been recomputed. It is to be hoped that there will be no further change in the practice in this matter; it can be assumed that the present values are accurate enough for any geophysical application, and we do not want further confusion owing to different workers using different values.

Full particulars of the known radioactive minerals are given, with an enormous number of analyses and age determinations from all parts of the world. The helium problems are also discussed. The helium/uranium ratio, though not very useful for finding the ages of minerals, seems to be coming into its own in application to complete rocks, from which the loss of helium by leakage is much less, and in the hands of Dubey and Günther this method is giving valuable results. A careful discussion of the needful precautions in interpreting lead and helium ratios is given. Future workers on geological time will certainly find Holmes's work indispensable.

The book begins with a short introduction by Prof. Adolph Knopf. Prof. Schuchert treats the older denudational and biological methods of estimating geological time, but also contributes one based on the maximum (instead of the mean) thickness of each formation and the rate of accumulation. This principle has already been applied by Reade and Goodchild, and gives results in general agreement with those derived from radioactivity. Schuchert goes rather further and draws a somewhat startling conclusion: that deposition in the Tertiary and Mesozoic was three or four times as fast as in the Palæozoic. We are used to the idea that post-glacial deposition has been abnormally rapid, but Schuchert thinks that the rate has increased steadily.

Prof. Knopf, in discussing the age of the ocean, mentions the possibility that the excess of sodium is removed from it by adsorption at the bottom. This would explain one great difficulty: how it is that the ocean, drawing its sodium and chlorine from independent sources, has managed to remain neutral throughout geological time. Prof. A. F. Kovarik gives a very elaborate account of the radioactivity data from the point of view of the experimental physicist; the values for the various constants that he finally decides upon as the best have been adopted in Holmes's section.

Most of the book deals really with the estimation of geological time rather than with the age of the earth. We are now in a position to compare directly the ages of formations in different parts of the earth by radioactivity, without reference to fossils, and therefore the new methods are available to make fundamental contributions to ordinary geology. If an igneous rock is found to have an age of 200 million years, we can say that its age is Permian even if there is no sedimentary rock near by between the Pre-Cambrian and the Tertiary.

Prof. E. W. Brown gives a brief account of astronomical clues to the age of the earth. Two of these, referring to the times needed for resonance phenomena to produce certain orbital features, are new. He suggests that my own estimate, based on the theory of the resisting medium, needs reinterpretation to allow for accretion on the planets; but as I suppose the medium to be hydrogen, the question of accretion does not arise. His general conclusion is that astronomical evidence is consistent with geophysics but less definite; and with this we may readily agree. HAROLD JEFFREYS.

A New History of Astronomy.

Die Geschichte der Sternkunde: von den ersten Anfängen bis zur Gegenwart. Von Prof. Dr. Ernst Zinner. Pp. xi + 673 + 13 Tafeln. (Berlin: Julius Springer, 1931.) 21·80 gold marks.

PROF. ERNST ZINNER is to be congratulated on having produced a captivating volume. What is most astonishing is the easy mastery with which he reviews the very different subjects that are contained in his work. There is here no heavy muster of facts, but enough to enable us to understand the lines of discovery and the development of ideas, the causes that contributed to progress, stagnation and decay, and the difficulties that had to be encountered. Astronomy is throughout brought into relation to the civilisation, the religion, the educational organisation, and the material environment of each age, and yet every important advance in observation, in theory, in apparatus is duly recorded. It seems strange to find combined in one book the beliefs of primitive peoples, the results of archæological research in Egypt and the Euphrates valley, the work of the Greek mathematicians, and of medieval schoolmen; the steady march of modern dynamical and observational astronomy, with a remarkable appreciation of the present position of research and of the conditions that govern research in all the numerous departments of present-day astronomy; and in each case the treatment is illuminating. It would be an achievement to have acquired such familiarity in a lifetime, but it may be noted that our author was only forty-four years of age when this volume appeared.

Not only the great astronomers of the past, but also most of the distinguished, and many of the less well-known, living astronomers are mentioned somewhere in this book. As the treatment is by subjects, not by persons, it is in some measure chance that determines whether a particular astronomer shall be mentioned by name or not. Unlike too many of his compatriots, the author shows no tendency to name the work of his fellow-countrymen in preference to foreigners. The catholicity of his interests may be illustrated by the fact that no fewer than four living alumni of the University of Oxford are mentioned. I have not attempted the task of enumerating the living alumni of Cambridge. The only trace of German national pride seems to lie in the use made of the word *Germanen.* The first fifteen parts of the book, comprising nearly the whole, profess to give the astronomy of different nations or races. The thirteenth of these, the astronomy of the *Germanen,* runs to 295 pages and includes the whole of modern astronomy, for, to our author, all nations that have received the German *Kultur* are entitled to be included under the generously comprehensive designation of *Germanen.*

What readers will miss most in this book is references. The author was probably right in omitting them. They would have added greatly to its bulk, and might easily have added many years to the labour of preparation. There is a general bibliography, six pages long, but, alas! it is arranged in alphabetical order by the authors' names and not by their subjects, and, what could probably not be helped, it includes only books, not papers. There is also a four-page bibliography of astronomical biographies, which ought to be valuable. Here and there bibliographical information is given in the text. But one would like to be able to trace the authority for some of the more speculative reconstructions of ancient science and ancient calendars, and to know, when results obtained by others are not accepted, whether the rejection is due to ignorance or considered judgment. For example, when Prof. Zinner devôtes nearly a page to the comets alleged to have accompanied the conception and accession of Mithridates, his rejection of my conclusions on that subject might be deliberate, but his failure to notice the passages cited by me from Si-ma Tsiän suggests that my discussion had escaped his notice. On the whole, it is probably more a merit than a defect that our author not only teaches his readers much, but also sets them hunting for his sources and for further information.

J. K. Fotheringham.

Qualitative Analysis by 'Spot' Tests.

Qualitative Analyse mit Hilfe von Tüpfelreaktionen: theoretische Grundlagen und praktische Ausführung. Von Dr. Fritz Feigl. Pp. xii + 387 + 2 Tafeln. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1931.) 28 gold marks.

Prof. Emich, the famous microchemist, has called "Tüpfelanalyse" "the qualitative analysis of the future", and looks forward to the time when there will be a specific test for every inorganic ion, with enormous saving of time and material in analysis. Dr. Feigl has written the first textbook on Tüpfelanalyse, or 'spot' tests, after ten years' research in the subject, and shows that the methods are not of the future alone, since already for almost every ion there are two or more 'spot' tests worked out in detail. There are several methods of complete qualitative analysis using 'spot' tests only, and one method, combining the tests with some of the older group separations, is already in use in the chemistry course of the University of Delft.

'Spot' tests all involve a colour change, and the apparatus is very simple, since the tests are all carried out either in test tubes, on a porcelain tile, or on filter paper previously impregnated with the reagent and dried. The reagents are mainly organic compounds. The author points out that one advantage of organic reagents is the higher molecular weight of the reaction products, which tend to be more visible than those formed with inorganic reagents.

The first part of the book is theoretical. Complex salt formation, which is involved in most of the tests, is discussed in detail. In an account of masked reactions, Dr. Feigl shows how an unspecific reagent may be made specific by the use of different solvents and by the addition of a reagent before the test which gives a complex salt with the interfering ions. An example of this is the thiocyanate test for cobalt in the presence of iron. The test is carried out in acetone solution and an alkali fluoride or syrupy phosphoric acid is added before the test to reduce the ionic iron concentration. In this way 1 γ of cobalt may be detected in a dilution of 1 : 50,000 in the presence of a thousand times the amount of iron. The possibilities of increasing the sensitiveness of a test by varying the conditions and by catalytic reactions are also dealt with.

There is an important chapter on induced reactions as they may be used to improve a test in qualitative analysis. The author gives a large number of examples, one of which is the barium test by sulphate precipitation. When the clear solution of lead sulphate in an acetic acid solution of an alkaline acetate is used as the precipitant for barium salts, not only is barium sulphate precipitated but also a considerable amount of lead sulphate, rendering the test eight times more sensitive, so that as little as 0·4 γ of barium in 1 : 125,000 dilution can be detected.

The chapter which has entailed the most detailed research is written on the organic groupings which react specifically with certain inorganic ions, the nickel specific $\begin{array}{ccc}-\mathrm{C} & - & \mathrm{C}- \\ \| & & \| \\ \mathrm{NOH} & & \mathrm{NOH}\end{array}$ group, the ferrous iron specific $\begin{array}{ccc}=\mathrm{C} & - & \mathrm{C}- \\ | & & \| \\ \mathrm{OH} & & \mathrm{NOH}\end{array}$ group, the $-\mathrm{CO}-\mathrm{CH}_2-\mathrm{CO}-$ group which is specific for thallium in the presence of carbon disulphide, the copper specific $\begin{array}{ccc}>\mathrm{C} & - & \mathrm{C}- \\ | & & \| \\ \mathrm{OH} & & \mathrm{NOH}\end{array}$ group, and the silver specific NH— group. A large number of compounds containing the different groups have been prepared, in order to discover the compounds most suitable to use for the tests.

There is a chapter on the effect of various organic groups on the solubility of the reaction product, and another on capillarity as it applies to spot tests, for the capillary properties of the filter papers are often of importance when two or three elements are to be detected simultaneously.

The practical section consists of a detailed description of the tests for all the inorganic ions. The tests are admirably described, being both complete and clear. The smallest amount of the element recognisable and the limit of dilution are given for each test; where other ions interfere, alternative procedure is given, and the largest amount of the interfering substance that may be present without disturbing the test. Where the reagents are rare, their preparation is described. There is a useful reference table at the end of the book summarising the tests and the reagents used. There are a few coloured illustrations, but as these are not clearly referred to the page and test illustrated, they are not very useful.

The book admirably achieves its object in combining both a book of reference and a practical handbook, and will therefore be valuable to all pure and applied chemists and everyone interested in the development of new methods of analysis.

Short Reviews.

La Grotte d'Isturitz. 1 : *Le Magdalénien de la Salle de Saint-Martin.* Par Dr. René de Saint-Périer. (*Archives de l'Institut de Paléontologie humaine,* Mémoire 7.) Pp. 124+13 planches. (Paris: Masson et Cie, 1930.) 120 francs.

As an archæological site the cave of Isturitz (Bayonne) was brought to the notice of Piette in 1895. Proposals for its exploration came to nothing. It was then being worked by a commercial company for its phosphates; and a series of objects of palæolithic age, which had been found in the course of the work, was given to the Société de Borda of Dax. Attempts were made to put a stop to the exploitation of the cave, but without success. A suit at law was instituted and the case dragged on until 1898, when a verdict was given against the company. Unfortunately, no injunction against further work had been granted while the matter was *sub judice*, and when operations ceased in 1898 the two galleries over which suit had been brought had been completely worked out. Valuable objects known to have been found, including examples of palæolithic carving and sculpture, have disappeared.

The opening of a second entrance to the cave on the death of the second owner, Dr. Langin, enabled systematic excavation to be begun in 1913. This was continued intermittently until 1921; but after that nothing further was undertaken until Dr. de Saint-Périer began operations in 1928. A second large series of related galleries was discovered in 1929. It is estimated that the complete exploration of the cave will take some years. In his desire to submit the evidence to his colleagues and to place the results on record at the earliest possible moment, Dr. de Saint-Périer has published this preliminary account of his excavation to date of the Magdalenian deposits of what he calls the "Salle de Saint Martin".

The conclusion to which the evidence points is that the inhabitants lived on the horse, of which they brought the joints and not the carcases to the cave. The horse is also the subject most frequently represented in their art. The cave was thickly populated, the climate dry and cold. The fauna and the culture alike point to early Magdalenian, the latter showing affinities with Tuc d'Audoubert, Les Trois Frères and Gantier, and corresponding with Lespugues *B*, the Magdalenian IV of the Abbé Breuil.

Archæologists will be grateful to the author for publishing his results with such commendable promptitude, even though his conclusions must be regarded as to a certain extent provisional, pending further excavation. Still more are they indebted to the Institut de Paléontologie humaine for the profusion of illustrations of high quality.

Elektrophorese, Elektroosmose, Elektrodialyse in Flüssigkeiten. Von Dr. P. H. Prausnitz und Dr. J. Reitstötter. (*Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe,* herausgegeben von Dr. Raphael Ed. Liesegang, Band 24.) Pp. xii + 307. (Dresden und Leipzig: Theodor Steinkopff, 1931.) 18·50 gold marks.

THIS is a very valuable book which will be of the greatest service to a wide variety of students and investigators, since it deals in a most comprehensive manner with a range of phenomena of equal interest to the physicist, chemist, and physiologist. To all those who are more particularly interested in colloid chemistry and physics the book will be indispensable.

The book is divided into five chapters: (1) General, (2) electrophoresis, (3) electro-osmosis, (4) electro-analysis, (5) technical applications. Throughout the book, and especially in the last chapter, special attention is paid to the extensive patent literature. This is a feature which will greatly enhance its value for the very large class of readers who are concerned with industrial processes and phenomena.

Although the authors refer the reader to the monograph on "Elektrochemie der Kolloide" (Pauli and Valko, 1929) for a fuller account of the theory of the subject, they give enough in the introduction and general part to enable the reader to understand the basic principles underlying the processes described. This portion of the book contains a description (with diagrams) of the various forms of apparatus employed in laboratory investigations —another very useful feature.

The documentation is extremely thorough and valuable. Thus the book concludes with 47 closely printed pages, embracing bibliography, patent register, author index, and subject index.

The work of Drs. Prausnitz and Reitstötter may be warmly recommended to all serious students of physical and colloid chemistry.

F. G. DONNAN.

The Paradox of the Ludicrous. By Prof. Samuel S. Seward. Pp. vii+145. (Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1930.) 12*s.* 6*d.* net.

THE real nature of laughter may be described as a standing scientific puzzle. Some of the greatest names in the history of philosophic thought, say from Hobbes to Bergson, are associated with attempts to solve the puzzle. Why do we laugh at the sight of a bishop running after his hat? Is it because we are at heart crowing over another's mishap? Or is it because a dignified person is being taken down several pegs? Or is it merely our reaction to an incongruous situation? Or did

Nature 'invent laughter' at minor misfortunes in order that man's vitality might not be sapped by an excess of sympathy? All these hypotheses, and others, have been tried, but none of them fits all the facts. For the facts are as disparate as laughing because one is metaphorically tickled by a joke, and laughing because one is literally tickled in the ribs.

Now comes Prof. Seward of Stanford University with his extremely interesting and well-written book, in which he says in effect that previous investigators have all been on the wrong tack, that they have all addressed themselves to the wrong question. Instead of seeking, as they have vainly sought, for a common quality in all causes of laughter, they ought to have been marking how the boisterous laughter of childhood leads on gradually to the quiet, mature chuckles at a joke in *Punch*. In other words, if we understand Prof. Seward aright, the evolution of laughter is an 'emergent' evolution. There we must leave the subject, but not without our reiterated appreciation of this excellent monograph. T. R.

Let's Help! a Collection of Good Causes. By Sir Charles Bright. Pp. xv + 198. (London: George Routledge and Sons, Ltd., 1931.) 4*s.* 6*d.* net.

In this volume Sir Charles Bright has brought together interesting information regarding numerous organisations which exist to further various kinds of good work. Among those described are a number of bodies engaged in extending the services of science in various directions, such as the British Science Guild and the National Institute of Industrial Psychology. The former was founded in 1905 by the late Sir Norman Lockyer to bring together all persons throughout the Empire interested in promoting the development and applications of science. The Guild has established numerous committees, such as those on the design and manufacture of microscopes, provision of glass and other laboratory ware, and the synchronisation of clocks. In 1921 it published a "Catalogue of British Scientific and Technical Books", containing 6627 titles, but in the 1930 edition the number of titles has grown to 13,915. Sir Samuel Hoare is president of the Guild and Sir Richard Gregory is chairman of the council of management.

The National Institute of Industrial Psychology, founded in 1921, has undertaken investigations under the direction of Dr. C. S. Myers for more than 180 firms representing nearly sixty different industries. Vocational tests have been devised and successfully applied to the selection of engineers, weavers, packers, chocolate makers, solderers, clerical workers, and many others. Research has also been carried out into problems of daily variations in efficiency, the nature of mechanical ability, and vocational problems of the blind. Numerous investigations have been made into the best methods of work in various occupations, but the error made by the pioneers of 'scientific management' in rigidly standardising movements has been avoided, since it is recognised that each worker, within limits, must develop his own style.

The Japanese Earthquake of 1923. By Dr. Charles Davison. Pp. xii + 127 + 6 plates. (London: Thomas Murby and Co., 1931.) 7*s.* 6*d.* net.

In this small volume Dr. C. Davison gives an intensely interesting account of the great Japanese earthquake of 1923 from two points of view: first, as it affected man and his works, and secondly, from the point of view of geophysics. The Japanese Home Office in 1926 issued a large report on the former aspect, and much of the first part of the book, including some interesting illustrations, is based upon that. The geophysical discussion summarises forty-one scientific memoirs, almost entirely by Japanese writers. Dr. Davison considers that though other earthquakes have been more violent, and some have taken a greater toll of human life, there has probably never been one that was so appalling in the total havoc wrought, largely because of the terrible fires that followed it. "In all probability there will never be another like it, for no city now exists with so many wooden houses as Tokyo contained in the days before the earthquake."

The story of the admirable behaviour of the populace in the midst of the disaster, and of the extraordinarily able and successful efforts of the Government in re-establishing the social organisation, is one of surpassing interest—perhaps the more so in view of the possible parallel man-wrought disasters of fire and explosion, if not of earthquake and tidal waves, that the future may have in store for other great capitals, if the nightmare threat of aerial warfare is not removed by international agreement.

Nuer Customs and Folk-Lore. By Ray Huffman. Published for the International Institute of African Languages and Cultures. Pp. xv + 108 + 8 plates. (London: Oxford University Press, 1931.) 8*s.* 6*d.* net.

Miss Huffman has lived for some years among the Nuer, members of the Nilotic group of tribes who are among the less accessible of the Sudanese peoples. Comparatively little is known about them, as they have a preference for their own ways, and, being slow to appreciate the advantages of European civilisation, have been able to preserve their state of reserve and seclusion. The author's thorough acquaintance with their language has enabled her to get closely into touch with them, and in this brief study she has set down much information which, if it does not give a complete account of their culture, is at any rate for the most part new. It is supplemented by an introduction by Dr. Westermann, giving a brief summary of the main features of their culture, which is dominated by their cattle tending and the periodic flooding of their country. The cult of what is apparently a rain deity holds a position of special significance in their beliefs. A number of folk-tales, in which the Nuer language is rich, is included.

The Evidence of Palæontology with Regard to Evolution.

A DISCUSSION on the extent and value of the contribution which the study of fossils can make to the study of organic evolution took place on Sept. 25 at a meeting of Section C (Geology) of the British Association. Even if it is agreed that palæontology is as incapable of providing a direct proof of evolution as is neontology, it must be admitted that palæontology reveals a whole series of facts which are correlated by that principle but are at present otherwise unexplained. It is generally agreed that the evidence of palæontology supplements that of neontology. Many palæontologists, however, would claim more than this for their subject; Prof. H. L. Hawkins emphasised that palæontologists see the problems of evolution in three dimensions, perhaps rather dimly, but claimed that a more satisfactory impression can be obtained in that way than from a sharper picture in one plane only, such as is ordinarily available for the student of living forms.

It is unfortunately true that in some respects the evidence which palæontology is able to contribute is scanty. Especially is this true in regard to the evolution of man, where fossil evidence does little more than supplement the evidence derived from the study of living Primates. Thus Sir Arthur Keith believes that from the fossil evidence alone we cannot construct man's genealogical history. The geological information is nevertheless important; "it permits us to verify and amplify the theory of man's evolution, which has been constructed from the evidence of anatomy, physiology, and embryology", but it is manifest that much more information is needed before our knowledge of man's origin rests upon a sound basis of ascertained facts. This incompleteness of the known fossil record of human evolution is emphasised by the different interpretations of the details of man's genealogy put forward by such authorities as Sir Arthur Keith and Prof. H. Fairfield Osborn.

In other groups of animals, however, and especially in those groups of mammals which have been investigated in such magnificent detail by Prof. Osborn, more complete series of fossils have been available, and the phylogenies of many families are reasonably clear. In such groups as the horses and the Titanotheres, the fossil record is at any rate sufficiently complete to warrant the assertion that the general lines of their evolution are moderately well known and can be demonstrated from fossil evidence.

In the case of the invertebrates also, the evidence of palæontology is of considerable weight, although the material available for study has certain obvious limitations, since the skeletons of the invertebrates are usually less closely related to the vital parts of the organism than is the skeleton of a vertebrate. Several of the speakers in this discussion claimed that, in spite of these disadvantages, invertebrate remains do afford valuable material for the study of evolutionary problems. The great numbers of specimens which are available for investigation make it possible to find series of specimens showing progressive changes in definite directions. The more abundant the specimens, the more completely may the seriation be demonstrated. In this way the palæontologist has been able to indicate certain series of invertebrate fossils which, in some cases, may accord closely to lineages or lines of evolution. The number of well-established lines among invertebrates (such as those of *Zaphrentis delanouei* and of the Chalk *Micrasters*) is admittedly small, for it is becoming increasingly clear that many so-called lineages are only approximations to lines of evolution, but there is abundant evidence of progressive changes by almost imperceptible gradations.

Many students of invertebrate fossils have paid great attention to the development of the skeleton during the life history of the individual. Certain invertebrates preserve in their skeletons a record of the changes in the skeleton during growth, for whereas the skeleton of a vertebrate is progressively modified during growth, the shells of many adult molluscs and the hard parts of many corals preserve unchanged the skeletons of the young individuals.

In the course of this discussion, several palæontologists (including Dr. F. A. Bather, Dr. W. D. Lang, Prof. H. H. Swinnerton, and the writer) emphasised the value of these ontogenetic characters in determining relationships—a value which has been recognised by palæontologists for many years. It was admitted that a more important criterion in establishing phylogenies is the recognition of transitional forms in a correct geological order, and that few palæontologists would propose to use ontogenetic evidence alone for constructing lineages. It was suggested, however, that, used with caution, ontogenetic evidence is of great value as a criterion of relationship. Dr. Lang maintained that some of the objections which have recently been urged against the recapitulation hypothesis are due to a failure to understand the views of palæontologists. He pointed out that not all the features seen in a developing organism (or preserved in the early part of its skeleton) are regarded by palæontologists as recapitulating adult characters; further, it is not an earlier adult *stage* which is normally represented in ontogeny, but rather certain individual *characters* possessed by an earlier adult.

Prof. Swinnerton emphasised the further importance of ontogenetic studies in relation to the behaviour of unit characters in development. He claimed that palæontology has important contributions to make to many of the problems which have been the concern of the geneticists. He pointed out that while palæontologists have studied more particularly those complex groups of characters which are represented in fossils by single structures (while the geneticist is concerned chiefly with unit characters), they have meanwhile accumulated much illuminating information relating to problems of inheritance. He suggested, moreover, that geneticists may too often have neglected the behaviour of those characters during development.

It may be remarked that Prof. D. M. S. Watson expressed grave doubts concerning the validity of the arguments used by some of the palæontologists who took part in the discussion. He especially deplored the use of ontogenetic evidence alone in the establishment of supposed phylogenies. He also criticised severely some current interpretations of the analyses of statistics relating to variability among invertebrate fossils, to which reference had been made.

In short, palæontologists are agreed as to the general extent and importance of the contributions of their subject to the solution of evolutionary problems; it is as regards the interpretation of the details of the evidence that there is much difference of opinion. A. E. Trueman.

The Gene and the Theory of Living Structures.

Dr. C. B. Bridges, whose name is associated with those of Morgan and Sturtevant in the now classical studies on the cytogenetics of *Drosophila*, and who recently went to Russia for a stay of some months, gave an address before the Genetical Society on Oct. 19, on the subject of "The Gene and the Theory of Living Structures".

Dr. Bridges led up to the question of the gene by a general discussion of scientific method. His general method of approach is an analysis from two aspects, that of structure and that of behaviour. This analysis is made at successively deeper levels, each simplification of the unit reducing complexity of structure; or, looking at it the other way, each change from a lower to a higher unit offering new possibilities of complexity not necessarily predictable at the lower level. Thus a crystal of sugar is successively analysable into sugar molecules, atoms arranged in a definite space-lattice, electrons, etc., composing the respective atoms. Reversing the process, the electrons must have preceded the atoms, the atoms the molecules, thus giving rise to evolution by progressive stages of aggregation, each stage presenting a fresh type of complexity. This might be called a form of the doctrine of emergent evolution; only the emergence is as true in the case of non-living as of living things. Of course, there is some disintegration as well as integration, but there is no reason to suppose that the process of integration is at an end, that the clock is running down; indeed, one might suppose that the time clock will only stop when it is wound up as tight as it will go.

At each stage of emergence, then, new characters arise which are not simply related to the properties of the components. Further, all these existences are affected by external conditions. The sciences describing matter and its properties may approach from the point of view of structure, like chemistry; or of behaviour, like physics: thus forming, as it were, a warp and weft of knowledge. Any simplification in the expression of structure calls for a corresponding complication in the expression of behaviour, and conversely.

The particular aspect of this evolutionary process which is presented to us depends on our local time and space. We have traditionally our three 'kingdoms'—animal, vegetable, and mineral; they might easily be two only, biontic and abiontic; and at some stage there must have been one only, the abiontic. Life exists only at certain levels of evolution and has no meaning outside these, just as temperature has no meaning below the molecular horizon, as it is a symbol of molecular activity.

What, then, is the essential property of living organisms? It lies in the manner of their reproduction, which is always continuous in time and space with an existing organism, and always autocatalytic in form. The process characteristic of living organisms is increase in spatial boundaries followed by splitting, either of the whole unicellular organism or, in higher plants and animals, of 'delegated' cells. It is clear that the machinery which brings about this type of multiplication must be as simple as a single cell. The significance of the nucleus in heredity is shown by the fact that the paternal influence equals the maternal in animals, where the sperm consists almost entirely of nuclear material, scarcely any cytoplasm being carried over into the new zygote. Taking the analysis a stage further, we find the nucleus formed from smaller bodies, the chromosomes, and the chromosomes in turn composed of still smaller particles, the genes. The genes correspond to the hypothetical units used by Mendel in his classical researches.

Now, when in the genetic investigation of *Drosophila* about twenty pairs of characters had been found, the fly having four pairs of chromosomes, it became clear that some of the chromosomes must carry more than one pair of factors. From this was developed the theory of the linear order of the factors and the conception of the gene as a particle having a definite place on the chromosome thread. The theory was confirmed by the discovery of non-disjunctions and of translocation: the genes in the translocated portion, said Dr. Bridges, have moved into a new street and have a new street number.

The actual size of a gene is probably of the order of 2.7×10^{-6} cm., smaller than any observed chromosomal structure. Probably each gene forms the central core to a body consisting of a skin and a core with chromonemal sap between. When the chromonema, which lies coiled in the chromosome like a spring in a tube, is uncoiled from its spiral it may be seen as a tangled skein bearing little knots; so if we cannot see the genes, we can see, as Dr. Bridges said, the tiny houses they live in. From Muller's X-ray work, which shows that a gene affected by irradiation is turned over at one stroke, the structure of the gene would seem to be simple and not compound.

What is the physical rank of the gene? It cannot be below a molecule, and must be built up from the molecules available in the nutrient sap surrounding it. It may possibly be a molecule of a new and unexpected type.

As regards the process which gives rise to two genes in place of one, two theories are mechanically possible. Either the daughter gene may be built up by the side of the old one, at a catalytic surface, with a point by point correspondence, or the original gene may become doubled and then split. The first would lend itself to a sort of 'zip-fastener' pattern with linear sub-units, as postulated by Serebrovsky. In Dr. Bridges' view, however, the phenomena described by Serebrovsky can be satisfactorily explained on lines of developmental mechanics without the postulate of linear sub-units of the gene. The gene might be a structure shaped like a pancake, having a single layer of molecules built into a definite pattern. A difficulty in the way of assuming that the daughter gene is formed at the surface of a vesicle as repetitions of unitary patches is the fact that genes mutate suddenly as if acting as simple units.

It is probable that the structure of all genes will be found to be of one type. This follows from increasing simplicity with descent in the scale of units. There is far less difference between chromosomes than between organisms, and hence probably far less difference between genes than between chromosomes. H. S.

New Game Reserves in South Africa.

By Prof. H. B. FANTHAM.

THE conservation of the natural fauna of a country is a matter of considerable importance. With the advance of agriculture and industrial development, the animals of South Africa, as in other parts of the world, have been in danger of extinction. In fact, within the last hundred years, six of its unique species, the bloubok, quagga, Namaqualand giraffe, Orange River buffalo, black-maned Cape lion, and the red hartebeest, have become extinct in the Cape Province, and many other species are in danger of extinction. The blesbok, bontebok, and white-tailed gnu only occur on private lands and have been preserved through the efforts of a few individuals.

The South African Government has not been unmindful of the interest and value of its fauna, and a number of large and important game reserves have been established, of which the Kruger National Park in the Transvaal of 5,000,000 acres (more than 7000 square miles) in extent, and the Umfolosi Reserve in Zululand—the home of the fast disappearing white rhinoceros—are perhaps the best known. Recently, on July 3, the Government of the Union of South Africa proclaimed three new game reserves, the constitution of which had been approved by Parliament on May 8.

The largest of these new reserves is termed the Kalahari Gemsbok National Park, in the Division of Gordonia, some distance north of Upington. This Kalahari reserve is about 1,800,000 acres (some 3000 square miles) in extent. It is an arid area, situated in the Kalahari thorn country between the Oup (Aub) and Nosop (Nossob) Rivers. The elevation is 2000-4000 ft. The vegetation consists mainly of thorn bush (species of *Acacia*), thorn-trees such as the cameeldoorn (*Acacia giraffæ*), which is the most characteristic tree of the region, and sparsely spaced tufts of desert grasses. The rivers are frequently dry sandy beds, which flow after rain, but water can always be obtained by sinking shallow wells. This reserve shelters a number of vertebrates, which feed on succulents and xerophytic vegetation, on which they thrive. These include the graceful and handsome gemsbok (*Oryx gazella gazella*), the red hartebeest, the blue wildebeest, and the springbok. The gemsbok was formerly widely distributed in southern Africa, but now has become relatively rare and even extinct in many parts of the country. They flourish in the Kalahari wastes, where they roam in herds and feed on succulent roots and underground stems dug out by their hoofs. Under protection in the new reserve they should increase in numbers. In addition to the antelopes mentioned, the kudu occurs in the reserve, klipspringer are said to be present, and wild ostrich are known.

The second reserve is the Addo Elephants National Park in the Divisions of Alexandria and Uitenhage, Eastern Cape Province. It comprises an area of more than 11,000 acres, well covered with dense scrub and bush. Portions of the Union Forest Reserve and of a number of farms have been combined to form this game reserve, where the now small herd of the southern geographical race or subspecies of the African elephant can live and propagate. Abundance of *Acacia*, succulent *Portulacaria*, aloes, and other succulents provide ample food. A few years ago the Government was obliged to reduce the herd greatly, as they invaded neighbouring farms and did considerable damage. The presence of good watering places in the new reserve, it is hoped, will prevent further damage to cultivated lands by these interesting small elephants. Cape buffalo, which were almost exterminated by rinderpest, still survive in the Addo reserve, and kudu and bushbuck occur in herds. A similar race of elephants occurs in the Knysna reserve, comprising the finest indigenous forests in the Union, and in both the Knysna and the Addo wild pig are abundant, accompanying the elephants and feeding on their droppings, thus aiding in the dispersal of the seeds of trees.

The third reserve is styled the Bontebok National Park. It is situated in the Division of Bredasdorp in the south-western Cape Province. It is a small reserve, some 1700 acres in extent, and will be a sanctuary for the rarest of the South African antelopes, the bontebok (*Damaliscus pygargus*). For many years this small but most beautiful and richly coloured antelope has been confined to a few farms in this area and has been preserved through the efforts of a few individuals. Formerly it was widely distributed along the coastal strip, and without the active interests of the animal lovers already mentioned it would, without doubt, have become extinct. It is highly important that the bontebok, the only indigenous large mammal of the south-west Cape, should be given a permanent refuge.

From my friend, Dr. E. Warren, Director of the Natal Museum, I learn that the mountain zebra at Cradock are still not adequately protected. These animals are more beautiful than Burchell's zebra, and have adapted themselves to mountain life and bleak stony wastes. It has been suggested by Sir Lionel Phillips that they should be established in a reserve at Bain's Kloof, and, for the sake of posterity, it is to be hoped that a mountain zebra reserve will be proclaimed in the near future.

News and Views.

AMONG the many members of the Society of Jesus who have added to scientific knowledge, few were better known than the seventeenth century natural philosopher Franceso Terzi de Lana, the tercentenary of whose birth falls on Dec. 13. Like his friend and contemporary, Father Kircher, Lana published various works among which was his now very rare book, "Prodromo, overo Saggio di alcune Inventioni . . ." of 1670. In this, he described a series of useful discoveries and it has been called the first book of the science of aeronautics. To raise oneself in the air he suggested the use of four thin metal spheres exhausted of air and attached to a car. The experiment was never made, but Lana's ideas foreshadowed the balloon and airship. His other work of note was his "Magisterium Naturæ et Artis . . .", in which he intended to cover the entire field of the natural sciences; only three of the intended nine volumes were issued, but these have been referred to as "a veritable cyclopædia of all sciences connected with natural philosophy". Born at Brescia, Lana entered the Society of Jesus in 1647, studied at the Roman College and afterwards taught at Terni, Ferrara, and elsewhere. When his health began to decline, he returned to his native city and died there on Feb. 22, 1687.

ON Wednesday, Dec. 2, in the University Museum, Oxford, Prof. E. Freundlich, director of the Astrophysical Observatory at Potsdam, delivered a lecture on the results of the Potsdam Solar Eclipse Expedition to Sumatra in May 1929, to determine the deflexion of light in the sun's gravitational field and to examine its variation with distance from the sun. Dr. Freundlich dealt solely with the results obtained from the series of plates exposed in one of the two telescopes which were employed at Sumatra. Four of these plates were exposed on the star field immediately surrounding the sun and the remaining three on a star field at a distance of 25° from the sun. Exposures on the same star fields were also made at the same place some months later and at night. In order to obtain the highest possible accuracy it was not advisable to measure the distance apart of two star images on the eclipse plate and compare it directly with the corresponding distance on the night plate. Plates exposed so as to obtain laterally inverted images of the star fields were adopted as intermediate standards of comparison.

PROF. FREUNDLICH showed that after corrections for aberration and refraction had been made, the star image displacements could be expressed as the sum of two terms, one, the scale effect term due to small variations in focal length of the observing telescope, and the other due to the actual light deflexion. The change in focal length is primarily a temperature effect. It manifests itself in the same way as the light deflexion, that is, it gives rise to a dilatation, which, however, increases with increasing distance from the sun, whereas the light deflexion effect decreases. Unfortunately, the weight of the coefficient of the scale effect term is approximately two hundred times greater than that of the light deflexion term, but by superimposing on each plate the image of a specially prepared ' reseau ' placed at the focus of a collimating lens, Prof. Freundlich and his collaborators were able to differentiate between the two terms and obtained the value $2{\cdot}24'' \pm 0{\cdot}20''$, instead of the value $1{\cdot}75''$ as predicted by theory for the deflexion of a beam of light in the sun's gravitational field. A recalculation of the results of the Lick expedition paying particular attention to the influence of the scale effect term yielded a value of $2{\cdot}2''$. A revision of the field equations of the theory of relativity would appear to be of the highest importance.

DURING the last few weeks, much interest has been aroused by the discovery of fossilised remains of the mammoth (*Elephas primigenius*) near Nottingham. Similar remains have been found, from time to time since the middle of last century, at other places in the vicinity of the city. Unfortunately, nearly all of these have been lost or destroyed. Even so recently as three years ago, a complete skull was found and promptly destroyed by the workmen, and only a small fragment of one of the tusks was rescued. It is hoped that the publicity given by the newspapers to the present find will result in a more enlightened treatment of such remains in future. The Trent Gravel Company's workings are in a patch of the older river gravels, situated half a mile away from the river Trent at Attenborough. These gravels were deposited after the last erosional phase of the river and now underlie its present flood plain. The remains which were recently found consist of one tusk five feet long, a third upper and a corresponding lower molar. They were found twenty feet below the surface, in the bottom layers of gravel. One molar was much worn by rolling, and must therefore have been derived from older deposits. The condition of preservation of the other, and the fact that it had not been rolled, show that it was contemporary with the gravel in which it was embedded. It thus furnishes additional testimony in favour of the view that the mammoth survived into post-glacial times in Great Britain.

A remarkable group of meteorite craters near Henbury in Central Australia was explored in May 1931 by Mr. A. R. Alderman, of the University of Adelaide, and his account of them was given before the Mineralogical Society on Nov. 3 (see Nature of Dec. 5, p. 977). Later, in June of this year, a second expedition to the locality was undertaken by Mr. R. Bedford, of the Kyancutta Museum at Kyancutta, South Australia, who travelled about 3000 miles by motor truck. Numerous masses of meteoric iron, weighing from a fraction of an ounce up to 170½ lb., have been found scattered around the thirteen craters, and 1350 pieces were collected by the two parties. A selection of the 542 complete masses of the iron, together with his sketches and photographs of the craters, recently sent by Mr. Bedford to the British Museum, are now on view in the meteorite pavilion of the Natural History Museum at South Kensington, as a temporary loan exhibit from the Kyancutta Museum. In the report in Nature of Mr. Alderman's paper, the last sentence should read: These craters, which are very similar to the famous Meteor Crater in Arizona, though much smaller, were evidently formed by the impact of a shower of meteorites at some remote period.

At the meeting of the International Seismological Association in Stockholm in 1930 a committee under the chairmanship of Commander Heck of the United States Coast and Geodetic Survey was appointed to consider what modifications are desirable in the code used for seismological telegrams or broadcast messages. It is now announced that a provisional code has been adopted and will be brought into use as from Jan. 1, 1932. The code will be submitted to the Association for approval or modification at the meeting which is to be held at Lisbon in 1933. The principal departure from the code in use hitherto is that provision is made for reporting phases other than P and S. Originally the letters P and S signified merely the first and second conspicuous disturbance in an earthquake record, but more precise meanings are given nowadays. For example, if a station is about 110° from the epicentre, the first phase on the record may be PR_1, a longitudinal wave reflected at the surface, whilst the next clearly defined phase may be S_cP_cS, a wave which is initially and finally transversal, but longitudinal in the central liquid core of the earth. With the new code the times of these or other pairs of phases can be reported. The other new feature of the code is the inclusion of check groups. The check figures are obtained by adding figures of the significant groups according to specified rules. When the figures tally, the recipient may be certain that he has a correct message, and experience with similar check groups in meteorological broadcasts shows that when figures do not tally the recipient has a reasonable chance of discovering what error has been made. Copies of the code may be obtained by application to M. E. Rothé, director of the International Seismological Bureau, 38 Boulevard d'Anvers, Strasbourg.

On Nov. 30 an interesting experiment in electric traction was carried out on the Great Southern Railways Company's line from Dublin to Bray, when a special train driven by current supplied from Drumm storage batteries was successfully tried. The train was 135 ft. long and weighed 75 tons, and an average speed of thirty miles an hour was maintained. The battery, which is the invention of Dr. J. J. Drumm, of Dublin, is of a new design, its special feature being that it is capable of supplying a heavy discharge during periods of acceleration, and of being rapidly charged to its full capacity. Though full particulars of the battery have not yet been published, information regarding it was issued by a department of the Irish Free State Government during preliminary tests made about a year ago. The positive plates of the cells are of nickel and graphite, but the negative plates appear to be of nickel gauze. The containers are of monel metal and the electrolyte is stated to be mainly a solution of caustic potash in distilled water. A party of experts, with Mr. P. J. McGilligan, Irish Free State Minister for Industry and Commerce, travelled in the train on Nov. 30, and all expressed their satisfaction with the results of the trial. It is hoped that by the use of the Drumm battery it will be possible to electrify the Irish Free State railways at a comparatively small cost. An account of the preliminary tests was published in *Engineering* for Sept. 5, 1930.

A new departure has been made at the Science Museum, which is visited by many thousands of children annually, by providing a gallery specially planned to be attractive and interesting to them. The descriptive labels of objects in the main galleries are for the most part scarcely within their grasp, and consequently their interest in the objects is not aroused. In the new Children's Gallery, which will be opened to the public on Dec. 12, illuminated perspective scenes are freely used, and these are supplemented by working models. One series of exhibits illustrates the development from man-transport through various types to the mechanical transport of to-day; another shows how primitive forms of lighting have been successively replaced by more efficient methods. Three of the earliest of human crafts, the flint tool-maker, the potter, and the smith, are represented, and films of each at his work will be shown. With each exhibit is a reference to the Museum Gallery in which similar objects are to be seen. Time measurement, the making of a pot, and a model aeroplane in a wind channel are also included in the exhibits; illuminated transparencies show astronomers at work; alchemists and modern chemists' shops are compared; and the development of the aeroplane is sketched.

The United States Patent Office has issued the specification of the first plant patent to be granted under the new provisions which were added to the patent law last year. The revised statute states that a patent may be granted to " any person who has invented or discovered and asexually reproduced any distinct and new variety of plant other than a tuber-propagated plant ", and that the patent shall grant to the inventor " the exclusive right to asexually reproduce the plant ". The law applies, therefore, only to the production of new varieties by grafting, budding, etc., and not by seeds. The patentability in any particular case will be determined according to the ordinary principles of patent law, but it is clear that a new plant must have characteristics which clearly distinguish it from known varieties, whether those characteristics relate to colour, immunity from disease, flavour, perfume, resistance to cold or heat, storage qualities, and so on. The specification of Plant Patent No. 1 granted on Aug. 18, 1931, is for the climbing rose 'New Dawn', which is stated to be distinguished from the 'Dr. Van Fleet' by its ever-blooming habit, and when grown in the latitude of New Brunswick, N.J., to provide "a succession of blossoms on a single plant from about the end of May to the middle of November or until stopped by frost".

IN connexion with the project, fostered by the Canadian Government, for establishing a regular steamship service during the summer navigation season between Churchill, the new port on the western coast of Hudson Bay, and Europe, which was described in an article in NATURE for July 11, p. 53, it is of interest to record that test shipments of grain, amounting to 545,000 bushels, were loaded and cleared from the port on Sept. 18 and 22. No further transport movement has been attempted this year, but it is hoped to bring the port into regular operation in 1932. The point of crucial importance is the duration of the navigable season in the Strait and Bay. In the report of Capt. N. B. McLean, quoted in the article above referred to, the period of free navigational movement was given as about four months, between the dates of July 19 and Nov. 16. This tentative conclusion was based on observations made on the formation and prevalence of ice during the seasons of 1927 and 1928. A report is now to hand on the "Navigable Conditions in Hudson Bay and Strait during the 1930 Navigation Season", from which it appears that the Strait had become fairly clear of ice by the last week in July, though there was "heavy, close-packed ice" at Burwell on July 25-26. At Nottingham Island Direction Finding Station, no ice of consequence was observed after July 24. Churchill harbour was free from ice so early as June 11, and ice was apparently not again formed until Oct. 19. The first ice which might affect navigation on the Hudson Bay route was reported on Oct. 16 by the Nottingham Island Station, and on Nov. 4 at the same station there was "heavy, close-packed ice as far as could be seen". As regards fog, between Aug. 2 and Oct. 31 there were about seventy hours' dense fog and from 20 to 50 hours' light fog, according to locality.

FURTHER news is to hand of the investigation of the Oldoway bone beds by the East African Archæological Expedition which, under the leadership of Dr. L. S. B. Leakey, has accompanied Dr. Hans Reck to the site on which the latter discovered the Oldoway skeleton in 1913. According to a dispatch from Nairobi in the *Times* of Dec. 3, stone tools have now been discovered in all five of the bone beds. It will be remembered that when Dr. Leakey and Dr. Reck addressed to NATURE the joint letter which appeared in the issue of Oct. 24, p. 724, Bed No. 2, to which it had been determined that the skeleton belonged, had yielded only two flakes showing bulbs of percussion, while the overlying beds 3 and 4 had yielded unrolled coups-de-poing typical of late Kenya Chellean and Acheulean. It would now appear that in Bed No. 2 early Chellean implements have been found in the lower layers and advanced Chellean at the top, while Beds 1 to 4 provide a complete sequence from pre-Chellean to advanced Acheulean. It is also stated that part of an articulated skeleton of a deinotherium, usually regarded as of miocene age, was discovered in a bed associated with pre-Chellean implements in conditions which preclude the possibility that it is derivative. Confirmation and fuller details must be awaited; but it does not necessarily follow that an extremely high antiquity must be attributed to the artefacts. Although Prof. J. W. Gregory has assigned certain beds which he correlated with Kumasian deposits to the Miocene, this classification is not accepted in Dr. Leakey's recent book. The members of the Expedition are inclined to regard the Oldoway beds as of lower and middle pleistocene age. In any event, a much higher antiquity is attributed to *Homo sapiens* than has previously been accepted. Dr. E. J. Wayland's letter on p. 1003 of this issue should also be read in this connexion.

IN the American journal *Engineering and Contracting* for September 1931 is a reprint of an interesting article by Col. T. T. P. Luguer, of the Corps of Engineers Reserve, on Mason and Dixon's Line, which was first published in the *Military Engineer*. Charles Mason, who was born in 1730 and died in 1787 and was assistant to Bradley and to Maskelyne, was engaged with Jeremiah Dixon in 1763 to settle the boundary controversy between Pennsylvania and Maryland, which had raged with exceeding bitterness for a century. Col. Luguer gives a sketch of the history of the boundary dispute, which involved among other things a lawsuit in the Court of Chancery lasting fifteen years, and describes the methods used by Mason and Dixon, and the fixing of the boundary marks. There were many difficulties and dangers to be overcome, and on Oct. 9, 1767, having proceeded a little more than 230 miles from the northeast corner of Maryland, the Indians refused to permit the line to be run farther. The accuracy of the work was good, considering the apparatus used, and at the last survey, about twenty-five years ago, the maximum deviation from the true parallel was found to be about 1000 ft., and that for the greater part of the distance the errors were very small. A special report on the resurvey of the Maryland-Pennsylvania Boundary was published by the State of Pennsylvania in 1909.

AT the Crystal Palace Show in the third week of November the most interesting section was that of the fur-bearing mammals, of which were exhibited not only the usual variety of rabbits, but also choice colour varieties (silver and 'cross') of the common fox, the form of the Arctic fox which remains coloured in winter, musk-rats, coypus, polecat-coloured ferrets—dignified by the title of 'fitch'—and in particular, specimens of the mink, an animal not at all common in zoological collections, and of particular interest as being intermediate in form and habits between the otters and the terrestrial weasels. The show of poultry was not so interesting as that of the Poultry Congress at the Crystal Palace last summer, because there was the usual limitation of species—no guinea-fowls, whereof the Congress exhibited several species and hybrids, and only one specimen of the swan-goose (*Cygnopsis cygnoides*), commonly known in England as the Chinese goose. It is, however, the domestic goose of eastern Asia generally, being found in its least specialised form in India, and in China showing several breeds as distinct as those of the western greylag ; at the Congress most of these could be compared. The wild race of the swan-goose appears never to have been imported, and is little known.

IN the North Mammal House at the London Zoological Gardens can now be seen no less than three species of tree-kangaroos (*Dendrolagus*) from New Guinea, specimens of *D. matschiei*, which was only described for the first time in 1907, having recently been received. This is the brightest coloured of all kangaroos, having a body of rich bay, while the extremities are buff. A young one, about six months old and mostly independent of the pouch, is as bright as its mother. This species is rather small as kangaroos go, and so is the black tree-kangaroo, *D. ursinus*, which is strikingly quadrupedal in its movements and looks rather like a huge clumsy marten. The third species, the grizzled grey tree-kangaroo (*D. inustus*), is, however, a hopping biped like the ground-kangaroos and looks far more like them, though with small ears and a decidedly sheepish-looking head ; this is small in proportion to the body, which is of good ordinary kangaroo size. This species shows very plainly that the tree-kangaroos really display no approach to the phalangers, that approach being made by the little rat-like musk-kangaroo (*Hypsiprymnodon*) which has not yet been exhibited in England.

AT a meeting of the Section of the History of Medicine of the Royal Society of Medicine on Dec. 2, Dr. J. D. Rolleston disposed of a legend current in the medical profession and elsewhere concerning Sir Benjamin Ward Richardson, F.R.S., who died in 1896, when a sympathetic obituary notice appeared in NATURE for Nov. 26, 1896, p. 80. Although Richardson's work and even name are unknown to a large proportion of the present generation, his memory, according to Dr. Rolleston, is still kept alive by those interested in the alcohol problem, in the scientific investigation of which he was a pioneer, as shown by his paper read before the British Association in 1866; the establishment of model abattoirs, for the provision of which he founded a society ; and the biographies of medical men and natural philosophers which he published in the *Asclepiad*. The legend in question was that Richardson, with the fanatical zeal of a teetotaller, poured down the sink the contents of a priceless wine cellar, which had been left him by Sir Walter Trevelyan in 1879 "to be applied for scientific purposes". Richardson was much embarrassed by the gift, although he had numerous suggestions as to its disposal. Finally nothing was done, and the bottles and their contents, one of which was exhibited by Dr. Rolleston, remained in possession of Richardson's family. Last July, a large consignment was sent to the late Prof. W. E. Dixon at the Pharmacological Laboratory at Cambridge, where it still remains, Dixon's death having taken place before he was able to examine it.

THREE years ago a series of tests on street lighting was organised at Sheffield by the Department of Scientific and Industrial Research. The tests were carried out by a group of independent observers, and ten different street-lighting installations were examined. The analysis of the results indicates that there was a tendency to assess the degree of 'glare' by the amount of discomfort experienced rather than by the reduction of visual sensitivity. A further series of tests was carried out a year ago at Leicester. The results have just been published by the Department in Illumination Research, Paper No. 13 (London: H.M. Stationery Office). In this test a series of eight street-lighting installations was arranged in Leicester, and the observers had to assess, without using any apparatus, the relative advantages and disadvantages of the various systems of lighting. Particular attention was paid to general visibility, attractiveness, and glare. The results show that the order in which the eight installations were placed by various observers was identical so far as regards estimates of the visibility of objects on the roadway, the reduction of ocular sensitivity, and discomfort from glare are concerned. The agreement arrived at, however, was not in accordance with the results obtained by computing the ocular sensitivity by laboratory experiments. Apparently, in estimating glare in street lighting, observers are influenced mainly by the sensation of discomfort experienced. Most of the observers thought that the most attractive installation consisted simply of large diffusing bowls. It has to be kept in mind that the observations were made by pedestrians. It is possible that the driver of a fast-moving motor-car might come to other conclusions, as he is liable to be affected by considerations which do not apply to pedestrians.

THE annual general meeting of the Association for the Promotion of Co-operation between Scientific and Technical Societies and Institutions within the British Empire was held at Burlington House, London, on Dec. 1. The report, which was adopted, referred to the appeal for a central building in London issued in February of this year to the members of the constituent societies and institutions, in which it was stated that options had been secured for a limited period on a site near Westminster Abbey, and that an estimated sum of £350,000 would be required to defray the cost of the complete building, including the purchase of leases, etc. It was further mentioned that to complete the purchase of the leases it would be necessary to secure £100,000 in cash by June 24, 1931, when the options on the site would expire. A considerable response to the appeal was received, but the sum available by June 24, however, fell considerably short of the amount required in cash, and the Council of Management decided to allow the options on the leases to lapse. The acute financial and industrial conditions prevailing during this year, culminating in the recent crisis, have rendered it necessary for the Council to postpone a public appeal until national conditions have improved. Though regretting the consequent delay in proceeding with the central building scheme, the Council will not relax its efforts to bring the scheme to fruition at the earliest possible moment.

The British Engineering Standards Association has now been reorganised to permit of it dealing with standardisation questions in the chemical, engineering, building, and textile industries, these groups or divisions of industry being controlled by representative divisional councils of equal standing. A supplemental Royal Charter has been granted to the Association authorising this reorganisation and changing the title to the "British Standards Institution". The Institution is governed by a Grand Council on which the above divisions of industry have equal representation. This latest development in the standardising movement, which has grown enormously since the first committee was set up by the Institution of Civil Engineers in 1901 as the "Engineering Standards Committee", is a clear indication that industry as a whole has increasingly recognised the economic value of the work, and for the first time the chemical and allied industries are now possessors of the proper machinery for setting up national standards for chemical materials, plant, and apparatus, and for methods of analysis and testing. The British Standards Institution is an entirely independent body, in the closest touch with industrial requirements and modern technical knowledge, and with full government support but free from government control. It exists to assist industry by preparing British standard specifications based on what is best in present practice, and do not attempt to attain an ideal which might be too costly to adopt.

We have received a short communication from Mr. Alfred Rosewood, of San Francisco, on "Disasters at the Moon's Third Quarter". He refers, among recent earthquakes, to those of Tuscany on Sept. 4, Solomon Island on Oct. 4, and Japan on Nov. 2, all occurring within about a day of the moon's third quarter; and, among other disasters, to the fall of the Quebec Bridge on Aug. 29, 1907, and the failure of the St. Francis dam during the night of March 12-13, 1928, both within the same interval of third quarter. The coincidences, at first sight, are striking, but if we extend the survey over a longer period the relation vanishes. For example, of fifty-eight of the most destructive earthquakes of the present century, three (April 14, 1906, on Formosa, Nov. 10, 1922, at Copiapo, and Sept. 2, 1923, in Japan) occurred on the day before the third quarter, and two (March 17, 1906, in Formosa, and April 14, 1928, in Bulgaria) the day after. If we take two days before and after, the number is increased by three. Thus, destructive earthquakes are not more frequent about the time of the moon's third quarter than at other parts of its period.

The Registrar-General's Statistical Review, 1930; Tables, Part ii, Civil, has been issued (H.M. Stationery Office. Price 2*s*.). The chief subjects of its statistics are population, births, marriages and divorces, registers of electors, and populations of British Dominions. The marriages in England and Wales during 1930 numbered 315,109, a few less than the previous year, equal to a rate of 15·8 persons married per 1000 population. This rate is the highest recorded since 1921, notwithstanding the present economic depression, and it is of interest that 22 males and 699 females married at the age of sixteen years, the lowest legal age at which marriages may be solemnised. The births registered numbered 648,811, an increase over the previous year of 5138, though the rate remained the same (16·3 per 1000 population). This increase is probably accounted for by the high marriage rates of the last two years. The proportion of the sexes in the births registered was 1044 males to 1000 females.

The small-scale maps of the Ordnance Survey was the subject of a paper to the Royal Geographical Society by Brigadier H. S. L. Winterbotham on Nov. 9, in which he referred to various innovations and improvements in recent editions. The new relief edition of the 'one-inch' is well under way, and the Plymouth sheet has already been published. A new 'half-inch' map is also in progress which will have hill shading and contours. The 'ten-inch' map, which, among other claims to value, is an excellent map for the main roads, is shortly to be put on sale in one sheet, mounted on both sides so as to facilitate easy reference by the motorist. Other innovations which the Ordnance Survey is introducing include diagrams of large towns bound up with the relevant quarter-inch sheets, and attempts to label the main roads so that the passage from one sheet to another shall be simplified and entail no searching.

A scheme whereby the activities of immigrant insects may be more closely recorded has recently been formulated by the Hastings and St. Leonards Natural History Society. It is hoped to obtain detailed information concerning the influence of weather conditions on the route of flight, periodicity of migrations, the sex condition of the migrants, etc. A standard card for recording information has been prepared, and, at the beginning, only the commoner and more conspicuous migrants will be recorded. A number of the printed cards will be sent to anyone who wishes to co-operate in the work on application being made to Dr. Norman Ticehurst, 24 Pevensey Road, St. Leonards, Sussex. Specimens for dissection should be sent to Dr. C. B. Williams, The University, 10 George Square, Edinburgh.

The Christmas Lectures at the Royal Institution will be delivered by Sir William Bragg on "The Universe of Light", beginning on Dec. 29.

AT the conclusion of his leave of absence from England, Dr. B. A. Keen has resumed his duties as assistant director of the Rothamsted Experimental Station. For the past twelve months he has been director of the Imperial Institute of Agricultural Research, Pusa, India. His scheme of reorganisation of agricultural research has been accepted, and certain portions of it are being put into effect at once. As we have already directed attention to the drastic curtailing of research grants in India, it is satisfactory to record that agricultural research has not only escaped, but has even secured funds for an appreciable expansion of its activities.

THE following appointments in the Colonial agricultural service have recently been made by the Secretary of State for the Colonies: Mr. W. N. C. Belgrave, plant physiologist, Federated Malay States, to be chief research officer, Federated Malay States; Mr. N. Greenwood, agricultural chemist, Nigeria, to be chemist, Agricultural Department, Gold Coast; Mr. E. S. Garner, to be agricultural officer, Sierra Leone; and Mr. J. G. M. King, to be agricultural officer, Tanganyika Territory.

THE annual meeting of the American Ornithologists' Union was held in Detroit, Mich., on Oct. 19–23. The officers were re-elected for 1932 as follows: *President*, Joseph Grinnell, Berkeley, Calif.; *Vice-Presidents*, A. C. Bent, Taunton, Mass., J. H. Fleming, Toronto, Ontario; *Secretary*, T. S. Palmer, Washington, D.C.; *Treasurer*, W. L. McAtee, Washington, D.C.; *Additional Members of the Council*, James P. Chapin, Ruthven Deane, H. C. Oberholser, J. L. Peters, C. W. Richmond, T. S. Roberts, P. A. Taverner. The election of new members included three corresponding fellows: Albert Collin, of Helsinki, Finland; M. B. Kinnear, of London; and Ernst Mayr, of Berlin. The Brewster Medal, given biennially for the most meritorious work on American birds, was awarded this year to Mrs. Florence Merriam Bailey for her "Birds of New Mexico".

ACCORDING to a report issued by Science Service, of Washington, D.C., two workers at the State University of Iowa, H. S. Olcott and D. C. McCann, have found that carotene, the yellow colouring matter of the carrot, is transformed into vitamin A by the action of an enzyme contained in the liver. Experiments showed that carotene is destroyed and vitamin A appears when carotene is incubated with fresh liver tissue derived from rats lacking vitamin A. Further research showed that the change is due to an enzyme for which the name of 'carotenase' is proposed.

A GENERAL discussion on the "Adsorption of Gases" has been arranged by the Faraday Society, to be held at Oxford on Jan. 12–13. The general introduction to the discussion will be given by Prof. Hugh S. Taylor (Princeton). The discussion will be divided into three sections. Section I., on experimental methods, will be opened by Prof. E. K. Rideal; Section II., on kinetics and energetics, by Prof. H. Freundlich (Berlin); and Section III., on theories of adsorption, by Prof. M. Polanyi (Berlin). Among the foreign visitors are Dr. Chariton (Leningrad), Dr. H. Dohse (Ludwigshafen), Prof. H. Mark (Ludwigshafen), Prof. O. Volmer (Berlin), Prof. B. K. Bonhoeffer (Frankfurt), Dr. W. Frankenburger (Ludwigshafen), Prof. E. Hückel (Stuttgart), and Prof. A. Magnus (Frankfurt).

WE have received the August–October issue (vol. 17, Nos. 4 and 5) of the *National Medical Journal of China*. It is a parasitological number and contains a collection of twenty-two papers dealing with various aspects of the subject, clinical and scientific. Some of them are of considerable interest and importance, for China still offers a wealth of material for investigations on parasitic diseases. There is, however, no contribution on the subject of malaria, which still remains a formidable menace to public health in South China.

A WORK on the "Medicinal and Poisonous Plants of Southern Africa", by Prof. J. M. Watt, professor of pharmacology in the University of the Witwatersrand, and Dr. Maria G. Breyer-Brandwijk, is announced by the publishers, Messrs. E. and S. Livingstone, 16 and 17 Teviot Place, Edinburgh. The plants are being grouped under their natural orders, and their poisonous or medicinal effects are fully discussed. The book will be well illustrated and should be very useful to the medical man and pharmacist. Publication is promised in 1932 provided that a certain proportion of the production costs are guaranteed before going to press. The book is therefore offered at a special pre-publication price of twenty shillings post free. Subscriptions should be sent to the publishers.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An administrative assistant in the University College of Hull—The Registrar, University College, Hull (Dec. 16). A fellow in the Department of Coal Gas and Fuel Industries of Leeds University, for the prosecution of post-graduate research in gas chemistry—The Clerk to the Senate, University, Leeds (Dec. 17). A junior lecturer in chemistry at University College, Southampton—The Registrar, University College, Southampton (Dec. 17). A George Henry Lewes student in physiology in Cambridge University—Prof. Barcroft, Physiology School, Cambridge (Dec. 31). A professor of pathology in the Medical College, Calcutta, and bacteriologist to the Government of Bengal—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (Dec. 31). A senior lecturer in anatomy in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, 73 Strand, W.C.2 (Jan. 15). A scientific research fellow at Girton College, Cambridge, for research in mathematical, physical, and natural sciences, including engineering, medicine, and agriculture—The Secretary, Girton College, Cambridge (Feb. 1). A graduate assistant for physics and mathematics at Darlington Technical College—The Chief Education Officer, Education Offices, Darlington.

The Internal Temperature of White Dwarf Stars.

IT has recently been discovered by S. Chandrasekhar,[1] B. Swirles,[2] and R. C. Majumdar,[3] independently, that the opacity of a degenerate gas is very small compared with what would be computed for a classical gas at the same density and temperature, the ratio being an inverse power of Sommerfeld's degeneracy-criterion parameter. This discovery seriously affects estimates of the internal temperatures in white dwarf stars. It has previously been held that interiors of the white dwarf stars are amongst the hottest of stellar interiors; for example, Russell and Atkinson [4] remark that their internal temperatures must be of the order of 50 times those of a main sequence star built on the 'diffuse' model. Again, Jeans [5] says "it appears that the central temperatures of the white dwarfs must be enormously high, while those of giant stars of large radius must be comparatively low". This has given rise to the paradox that the coolest stellar interiors appeared to be the best generators of stellar energy, the hottest the worst. To quote Jeans [6] again, "... many of the hottest and densest stars are entirely put to shame in the matter of radiation by very cool stars of low density, such as Antares and Betelgeuse".

If, however, the opacity in the interior of a white dwarf is very low, the temperature gradient in the interior must be very small. In the limit of zero opacity (assuming also small conductivity) the temperature-distribution is isothermal. The degenerate core is therefore a mass at an approximately uniform temperature, and the value of this temperature is determined purely by the observed mass M and luminosity L and the intrinsic opacity κ_1 of the gaseous envelope which surrounds the core. On the 'generalised standard model', in which the energy-sources are uniformly distributed and the opacity takes a constant value κ_1 in the gaseous envelope, the temperature T' of the approximately isothermal degenerate core is, in the standard notation:

$$T' = \frac{(R/\mu)^{\frac{5}{3}}}{(\frac{1}{3}a)^{\frac{2}{3}}K}\left(\frac{\kappa_1 L}{4\pi cGM - \kappa_1 L}\right)^{\frac{2}{3}}. \quad . \quad . \quad (1)$$

For the observed mass and luminosity of the Companion of Sirius, T' is $0 \cdot 34 \times 10^6 \kappa_1^{\frac{2}{3}}$ degrees, or, even if we adopt the high value $\kappa_1 = 300$ for the gaseous envelope, the value of T' is only 15 million degrees. For smaller values of the envelope-opacity it will be still smaller. For an almost completely degenerate star the internal temperature is determined by the *photospheric* opacity in the thin gaseous envelope.

According to my conclusion that all stars contain a degenerate zone surrounded by a gaseous envelope, formula (1) applies to all stars. Stars with a high value of L/M have small, incompletely degenerate cores, in which the temperature gradients though small are larger than in completely degenerate cores. Formula (1) still gives the interfacial temperature between core and envelope, and is thus a lower limit to the central temperature. It follows that stars with large internal generation of energy, that is, large values of L/M, have very hot central cores. Such stars will not be built on the standard model, but the effect of concentrating the energy sources to the centre, keeping other parameters constant, is only to increase the central temperature. Jeans's paradox, therefore, completely disappears; the best generators of energy have the hottest cores, and this applies to stars of all types, from white dwarfs to giants.

This result is quite obvious physically. The gaseous envelope acts simply as a blanket the rôle of which is to keep the core warm. A high energy-generator surrounds itself with a thick blanket, which keeps it very warm; a low energy-generator with a thin blanket. The actual value of the temperature attained in the core depends naturally on the intrinsic opacity of the blanketing envelope.

The above considerations illustrate, by a particular example, my contention that we cannot discuss the internal state of a star without discussing the opacity of its outer layers. In the case of a completely degenerate white dwarf, to ignore the effect of the photospheric opacity would be to obtain an utterly false estimate of the internal temperature.

The above results were communicated to Section A of the British Association on Sept. 29, 1931, at the discussion on the evolution of the universe, but did not appear in the printed accounts. I may add that the full theory of the 'generalised standard model', now fairly completely worked out, affords possible explanations of many of the observed characteristics of the stars in general, including some of those summed up in the 'Russell diagram', the approximate 'mass-luminosity' law for non-dense stars, the occurrence of pulsating stars and Novæ, and the possible existence of several types of configurations for large M and L (O-type, giant M-type, N-type, etc.) stars.

Molecular Weights of the Proteins in their Native State.

MOST of the determinations of molecular weights of the proteins carried out in this laboratory by means of the ultracentrifugal method were made on material which had been subject to purification using ammonium sulphate as a precipitating or crystallising agent.[1] When trying to isolate the lactalbumin from cows' milk, we observed that no product homogeneous with regard to molecular weight could be prepared —the figures ranging from 12,000 to 25,000—and that the molecular weight increased during the process of purification.[2] A closer study of this phenomenon showed that the condensation is due especially to the action of the ammonium sulphate used for the 'purification'. The bulk of the native material in cows' milk from which the lactalbumin is formed has a low molecular weight, probably not exceeding 1000. This startling discovery made it an urgent task to re-examine as many of the proteins previously studied as possible without any chemical treatment at all or at least under conditions closely resembling those of their native occurrence. A short summary of the results so far obtained is given below.

Ovalbumin.—An extensive ultracentrifugal investigation of the white of hen's egg was undertaken by Mr. B. Sjogren. He found that the sedimentation constant of the egg-white diluted with 1 per cent sodium chloride is always lower than the sedimentation constant of the purified ovalbumin,[3] which is $3 \cdot 5 \times 10^{-13}$. Sometimes a sedimentation constant so low as $1 \cdot 5 \times 10^{-13}$ was observed, and sometimes values approaching that of purified ovalbumin was found. The cause of these irregularities has not yet been traced. The sedimentation constant for the egg-white from eggs which had been preserved in water-glass solution for one and a half years was the same as for purified ovalbumin. A solution of egg-white of low sedimentation constant gave the normal ovalbumin value after treating it with ammonium sulphate.

The study of egg-white will be taken up again, but it is already clear that the ovalbumin does not always exist in the egg in the same form as that of the 'purified' ovalbumin. On the other hand, it seems that ovalbumin of the normal sedimentation constant is sometimes present in the egg and is very easily formed from egg-white under the influence of such salts as ammonium sulphate. The molecular weight 34,500 is the upper limit of the condensation process,[4] which corresponds to a sedimentation constant of $3{\cdot}5 \times 10^{-13}$.

Hæmoglobin.—For the determination of the molecular weight of hæmoglobin, Fåhræus and I[5] prepared solutions by simple water hæmolysis of the blood corpuscles. Measurements were made both on electrolyte-free (dialysed or electrodialysed) solutions and on solutions to which had been added sodium or potassium chloride in concentrations of 0·1 to 1 per cent. In all cases the same molecular weight, namely, about 68,000, was found. Nichols and I[6] later determined the molecular weight of hæmoglobin which had been crystallised by means of ammonium sulphate and found the same value. It therefore seems that hæmoglobin is not affected by the ammonium sulphate treatment and really does exist in the blood corpuscles.

Serum Albumin and Serum Globulin.—The question of the real state of the serum proteins in the blood has been the subject of much discussion. At the present time the ultracentrifugal technique offers the best means of attacking this problem. Preliminary determinations by Mr. K. O. Pedersen, Mr. P. v. Mutzenbecher, and Miss Inga-Britta Eriksson have shown that serum diluted with 1 per cent sodium chloride solution gives a sedimentation constant which is of the same order of magnitude as that of purified serum albumin and purified serum globulin. When using the refractive index method for recording the sedimentation, indications of a double maximum corresponding to the sedimentation constants of the two serum proteins were found. The question of the individual existence of serum albumin and serum globulin in the native serum can probably be settled by means of the new high-speed ultracentrifuge which has recently been installed in this laboratory.

Amandin (determinations by Miss Inga-Britta Eriksson).—This substance was chosen as a representative of the oil-seed proteins. A 10 per cent sodium chloride solution extract of almonds showed a high molecular protein with a sedimentation constant of the same order of magnitude as that of purified amandin. The extract also contained a substance of much lower molecular weight, the presence of which prevented an accurate determination of the sedimentation constant of the former substance.

Phycocyan (determinations by Miss Inga-Britta Eriksson).—An aqueous extract of the alga *Aphanizomenon* diluted with 1 per cent sodium chloride solution showed a sedimentation constant of $11{\cdot}5 \times 10^{-13}$, identical within the limits of error with the value $11{\cdot}2 \times 10^{-13}$ previously obtained for purified *c*-phycocyan.[7]

Phycoerythrin (determinations by Miss Inga-Britta Eriksson).—An aqueous extract of the alga *Ceramium* diluted with 1 per cent sodium chloride solution gave within the limits of error the same sedimentation constant, namely, $11{\cdot}4 \times 10^{-13}$, as that of the purified *r*-phycoerythrin, namely, $11{\cdot}5 \times 10^{-13}$.

The proteins phycocyan and phycoerythrin therefore exist in the aqueous extracts of the algæ and probably also in the living cells with the same molecular weight, namely, 208,000, as in the purified laboratory products.

Hæmocyanin (determinations by Mr. B. Sjogren and Miss Inga-Britta Eriksson).—Blood from the vineyard snail, *Helix pomatia*, was studied both undiluted (protein concentration 3 per cent) and diluted with 1 per cent sodium chloride (protein concentration 0·1 per cent). The values for the sedimentation constant were in perfect agreement with those obtained previously for the purified hæmocyanin.[8] In dilute solution the value 98×10^{-13} was found for the blood as well as for the purified protein. It is obvious, therefore, that the hæmocyanin is present in the blood of *Helix* with the same enormous molecular weight, namely, 5,000,000, as in the purified hæmocyanin.

From the above determinations it seems justifiable to draw the conclusion that most of the proteins do possess the same molecular weight in their native state as in the purified laboratory products. On the other hand, there are cases where the protein exists in the form of a low-molecular pro-protein in the living organism and is brought into the shape of a real protein by the 'purification' process, especially by the action of such salts as ammonium sulphate.

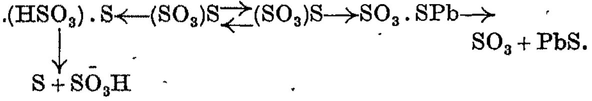
An Aspect of Co-ordination.

A CO-ORDINATE union between a bivalent atom, for example, of oxygen, and an atom or group *X* may be regarded as having resulted from the attachment of a neutral atom of the bivalent element to *X*, and its mode of formation frequently corresponds to this, although the transference of an already co-ordinated bivalent atom from another atom to *X* is a frequent variant of it. In any compound, therefore, the combination may be expected to behave as a composite atom or group, so that electronic effects, which in the original group would assert themselves at *X*, will assert themselves similarly in a qualitative, though possibly not quantitative, manner at the bivalent atom in the combination. For example, the composite thiosulphate ion, which is formed from the sulphite ion and sulphur, is stable only so long as it preserves its double negative charge, and breaks down into its components on partial or complete neutralisation. This, however, can occur in two ways, because there are two alternatively possible effective seats of the negative charge to which a cation may attach itself—the original ionic group or the attached sulphur atom:



$$\begin{array}{l}
(\mathrm{H\bar{S}O_3}).\mathrm{S} \longleftarrow (\mathrm{\bar{S}\bar{O}_3})\mathrm{S} \rightleftarrows (\mathrm{SO_3})\mathrm{\bar{S}} \longrightarrow \mathrm{SO_3.SPb} \longrightarrow \\
\quad\downarrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \mathrm{SO_3 + PbS.} \\
\mathrm{S + S\bar{O}_3H}
\end{array}$$

It might be expected that a cation of suitable intermediate character could be found which can attach itself in either manner, and this possibility appears recently to have been realised.[1]

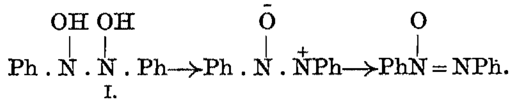
The salt formation of tertiary amines involves the lone pair of electrons on the nitrogen atom, and even when these are used in co-ordinating an oxygen atom, the capacity for salt formation is nevertheless retained in the resulting amine oxide. The oxides are recoverable from their salts, as are the amines :

$$R_3N + H\bar{A} \rightleftarrows [R_3NH]\bar{A}$$

$$R_3NO + H\bar{A} \rightleftarrows [R_3NOH]\bar{A}.$$

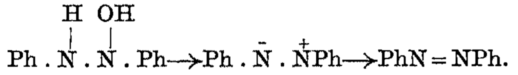
Although this is a particular case of the application of the principle of transmission of electronic effects by electrostatic induction, the implications attached to the relationships thus exemplified seem not to have been fully appreciated hitherto.

Thus, it will doubtless be agreed that the interaction of nitrosobenzene with β-phenylhydroxylamine will yield (I.) in the first place :



$$Ph\,.\,\overset{OH}{N}\,.\,\overset{OH}{N}\,.\,Ph \longrightarrow Ph\,.\,\overset{\bar{O}}{N}\,.\,\overset{+}{N}Ph \longrightarrow Ph\overset{O}{N}{=}NPh.$$

I.

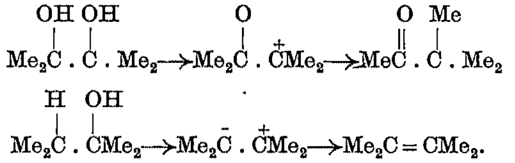


$$Ph\,.\,\overset{H}{N}\,.\,\overset{OH}{N}\,.\,Ph \longrightarrow Ph\,.\,\bar{N}\,.\,\overset{+}{N}Ph \longrightarrow PhN{=}NPh.$$

II.

Since, however, the lack of basic properties in azobenzene indicates that (II.) would at once break down into azobenzene and water, so (I.) at once furnishes azoxybenzene, and it will be noted that the modern, rather than the obsolete cyclic formula is thus deduced for the product.

The pinacone-pinacoline change has been the subject of extended discussion during recent years,[2] but does not seem to have been connected with the formation of azoxybenzene. Yet the grouping $>C\,.\,O$ may be regarded in the manner just discussed, and in fact the formation of *o*-nitrosobenzyl alcohol from *o*-nitrotoluene in presence of alkali must be regarded as proceeding by transference of a co-ordinated oxygen atom to a negatively charged carbon atom. The mode of formation of tertiary alcohols from their hydrocarbons also is probably of this kind.[3] The behaviour of pinacone towards acid therefore corresponds to that of methyl *iso*propyl carbinol, as indeed was suggested by Tiffeneau :



$$Me_2\overset{OH}{C}\,.\,\overset{OH}{C}\,.\,Me_2 \longrightarrow Me_2\overset{\bar{O}}{C}\,.\,\overset{+}{C}Me_2 \longrightarrow Me\overset{O}{\overset{\|}{C}}\,.\,\overset{Me}{C}\,.\,Me_2$$

$$Me_2\overset{H}{C}\,.\,\overset{OH}{C}Me_2 \longrightarrow Me_2\bar{C}\,.\,\overset{+}{C}Me_2 \longrightarrow Me_2C{=}CMe_2.$$

This view is also the basis of the electronic mechanism adopted by Robinson in regard to the reaction, but the present angle of approach seems worthy of record, since it may help to correct a not uncommon tendency to regard the pinacone change as something apart, rather than as essentially a particular case of the Hofmann decomposition of amines (as the dehydration of alcohols also may be considered to be).

Whereas, in the cases of the nitrogen compounds and of methyl *iso*propyl carbinol, neutrality of the product can be achieved by the sharing of a lone pair of electrons, originally present or resulting from the reaction, no such pair is available in the case of pinacone, and the necessary electrons can only be provided by transference at the same time of the group attached to them. This, it is suggested, is the real significance of Meerwein's demonstration that the Wagner and similar rearrangements are dependent on a cationic condition of the complex involved.

The above comparison between nitrogen and carbon compounds also lends point to the view that, in an entirely different field, the ortho-para directive properties of alkyl groups do not differ fundamentally in their origin from those of the amino-group, but correspond with the relative positions of carbon and nitrogen in the periodic system.

Cotton Growing in Egypt.

IN his review (NATURE, Oct. 31, p. 766) of recent publications on the working of the Seed Control Law in Egypt, Mr. Slater directs attention to the complementary nature of this law to the work of pure seed propagation carried out by the scientific staff.

As an agricultural research worker I very much doubt if it is correct to say that the cotton plant is the best studied agricultural crop. But with regard to legislation, it is probably true to say that no crop is subject to such an amount of careful legislative control as is the cotton crop in Egypt. Apparently the cultivator does not always know what is good for him, since attempts to evade the law appear to have been numerous. Perhaps it is unfortunate that the operation of the law has synchronised with a period of progressive market depression, so that it is not possible to make any estimate of the effect of the law from the economic point of view. Mr. Slater, who is in a position to know, does not comment on the effect of the law from the consumer's point of view.

These publications, unfortunately, do not give any information of a scientific nature on the principles underlying the working of the law, but it is said that the administration is indebted to the prevalence of a certain type of cotton plant known as Hindi which serves as an index of impurity. This Hindi cotton is recognised in the field by its white flower and general resemblance to American cotton. Its seed is quite naked, and except for its sharp point at the micropylar end is almost identical with the seed of Sea Island cotton. It thus possesses the characters of both its parents, Sea Island and American. The Seed Control Law operates only by excluding seeds of this naked Sea Island type. No account is taken of the lint characters, nor has anyone proved that the lint of naked seeded cottons is inferior to the lint of fuzzy seed cottons. I have seen evidence to the contrary, and also that cotton from fully fuzz seed is frequently inferior in spinning properties. From the genetic point of view, the Seed Control Law operates to exclude types resembling that of the best long staple parent, and propagates seed of full fuzz regardless of its lint quality.

Egypt certainly presents us with an interesting experiment in legislative control of an important crop. If the result is ultimately beneficial to the cultivator he will doubtless support it, but should it turn out to be nothing more than pseudo-scientific interference it will require more than scientific ingenuity to circumvent the evaders.

N. W. BARRITT.

Rothamsted Experimental Station,
Harpenden, Nov. 8.

In replying to Mr. Barritt, I am conscious of a feeling of uncertainty of what he wishes me to say to some of his veiled criticisms, largely levelled at the administrative policy of the Egyptian Ministry of Agriculture.

I may be wrong, but I fear Mr. Barritt has not quite grasped the meaning of the words 'quality' and 'uniformity' and their relative significance in a commercial commodity such as raw cotton. It appears to me that he is taking a very limited view of quality by ignoring uniformity, owing to his acceptance of spinning properties as the ultimate criterion of textile quality. I may point out that cotton is not only grown to be spun, but also to provide clothes which are acceptable to the wearer, who is becoming more critical year by year. Cotton which spun into the strongest yarn ever yet made would not find a market in one-hundredth part of the trade if it were so uneven that it would not dye to a level colour, or provide the many other desirable properties of a finished fabric.

The Egyptian Seed Control Law seeks to maintain uniformity in raw cotton by penalising those who attempt to mix seed-types. The consumer in Great Britain would not cavil at raw cotton which contains a low but constant proportion of Hindi cotton, but if there is no law to control that proportion, and the farmer is allowed to mix his seed according to his taste or fancy, it is difficult to see how the consumer is to benefit. If Mr. Barritt means that propagation of Hindi cotton or similar types would provide the consumer with better and more uniform fabrics at the same price, not stronger yarn, I am in agreement with him. At the same time, I must point out that Mr. Barritt puts forward no evidence other than a reference to spinning, which is only the beginning of the textile industry in Great Britain, to justify a complete reversal of the botanical policy of the Egyptian Ministry of Agriculture.

If I have answered Mr. Barritt's criticisms only from the consumer's point of view, it is because I believe the grower's and consumer's interests have much in common. I leave it to the Egyptian botanical experts to reply to his suggestions from the botanical side, but from my own experience I can say that mere mention of the Sea Island parentage of Hindi cotton is valueless as an indication of quality. Cotton grown from pure Sea Island seed in localities other than its native habitat is often inferior to cottons of lower pedigree. Moreover, the amount of genuine Sea Island (West Indian) cotton grown is ridiculously small, and yet there is more available than the textile industry is able to consume.

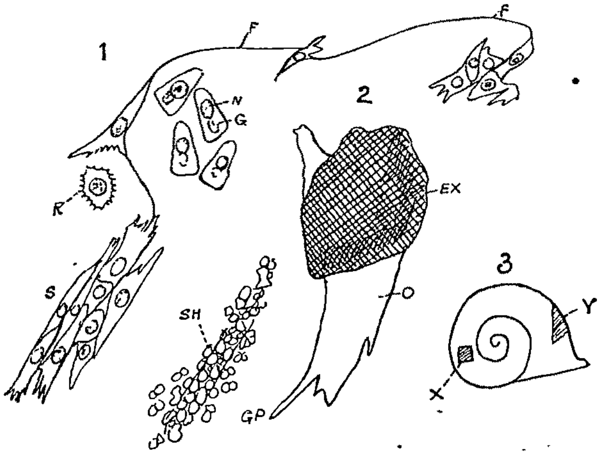
F. P. Slater.

Rock Bank,
Bollington, near Macclesfield,
Nov. 13.

Outgrowths from Pieces of *Helix aspersa*, the Common Snail.

In connexion with a cytological problem now being investigated, an attempt has been made to culture snail tissue. It is well known that snails are able to repair extensive injuries under what must be extremely septic conditions. The epithelium beneath the shell and elsewhere is not keratinised or otherwise protected, except perhaps for its faculty to produce mucus. It follows that such material might provide easy material for tissue culture, very careful aseptic precautions not being necessary.

Blood is procured from a snail by carefully cracking a hole in the shell, as shown in Fig. 3, *X*. A glass needle is stuck into the tissue and the blood wells up into the space between the shell and the snail, from which it is removed with a pipette. The front of the shell is peeled, *Y*, and pieces of mantle cavity epithelium with underlying tissue removed. These are cut up with a very sharp knife into ½ mm. pieces, in blood or Ringer solution, which need not be sterile. Indeed, except for flaming the coverslips and pipette, no aseptic precautions have been taken. A small drop of blood is put on the middle of a square coverslip and a piece of tissue (with as little Ringer solution in it as possible) added. The whole is sealed over a hollow slide, vaseline being used. Such preparations will grow out at room temperature (15° C. in my laboratory), but the best results are obtained at 25° C. in an incubator. I have also tried 30° C. Various forms of growth can be noted. Amœbocytes first come out (*F* in Fig. 1) and form a network of cells around the piece. After a day they form groups (*S*) apparently dividing and growing at the ends. Small round cells (*R*) also occur. By twenty-four hours the epithelial cells (*NG*) tend to come away from their layer, and flatten on the slide. Crystals (*SH*) now appear singly, and eventually join up to form long lines just beside the explant. These are at present regarded as shell material secreted by the epithelial cells. Now, besides this outward migration, in many cultures complete sheets of sub-epithelial connective tissue grow out, as in Fig. 2, *EX* being the explant, *O* the outgrowth, and *GP* one of the growing points, and also remarkable bulbous growths appear.



It seems important to wash the explant pieces in blood or Ringer solution before placing them in the blood on the coverslip. Apparently those bacteria, normally troublesome in vertebrate tissue cultures, do not interfere with growth in snail cultures, so that a person unused to the niceties of strict aseptic conditions should have no trouble in observing forms of growth in such snail cultures. Pieces of muscle keep alive and move spasmodically for as long as a week in such cultures. What seem to be very active outgrowth and division of both shell epithelial and vascular epithelial cells, has more recently been got as follows. The ordinary hanging drop preparation of mantle wall is made, and a piece of narrow coverslip added underneath, so that the explant lies between. All mantle cavity wall explants seem initially infected, but the bacteria keep in bounds for about three days, after which, unless the explant is well washed in blood, they multiply exceedingly. This account of some of the experiments can only be regarded as preliminary, as very little is known yet about the best conditions for this type of work on the snail.

In the epithelial cells *NG*, the Golgi apparatus (*G*) is very clearly to be seen *intravitam*, thus supporting the previous findings of R. Ludford [1] on the presence of this cell element in tissue cultured cells.

I am grateful to Miss Honor B. Fell for her courteous answers to inquiries about literature.

The Specific Heat of Ferromagnetics and Ewing's Model of the Magnetic Atom.

Prof. W. Gerlach has recently investigated the connexion between the spontaneous magnetism and the specific heat of a ferromagnetic, and he confirms the close relationship between them, pointed out by Prof. P. Weiss, which seems to imply the existence of an immense intrinsic magnetic field within a magnet. The magnitude of this field, however, is so large that there is a difficulty in accounting for its origin from observed magnetic values.

In a paper I submitted to the *Philosophical Magazine* of March 1922, an experiment was described which showed that an applied alternating magnetic field brings about a loss of ferromagnetism at a lower temperature than the normal critical temperature, leaving unaltered the temperature at which the specific heat suffers a sudden diminution, a temperature which is the same as the normal critical temperature for magnetism.

This almost certainly rules out the hypothesis that the large intrinsic field required to account for the specific heat changes emanates from the rotating magnetic element in a ferromagnetic substance. Hence the suggestion was made in the paper referred to that there must be two fields in a magnet interacting in some way on each other, one concerned with magnetic quantities as commonly observed and the other with specific heat changes.

Now Ewing's new model of the atom offers a possible solution of some of the difficulties mentioned above and supplies the double field required. In Ewing's words, " Each atom forms a magnetic system comprising a Weber element capable of turning, but controlled by magnetic forces exerted on it by other parts of the atom which are taken as fixed ". Mechanically, the model consists of a central pivoted magnetic needle controlled by bar magnets of equal strength, arranged radially in pairs at equal distances around the central needle with poles of one name all facing outwards. The poles pointing inwards produce an almost neutral control on the moving needle as required by the facts of magnetic induction, although the control magnets themselves may be very strong. To make this model fit the facts of ferromagnetism and abnormal specific heat we have only to suppose that it is as likely that the outwardly pointing poles of any atom will be north as south, and so one half the atoms may be supposed to have one polarity externally and the other half the opposite polarity. Between two atoms of opposite polarity there will be a strong attraction and a strong field, and they will tend to join together, forming molecules and groups of molecules. Such molecules or their component atoms, when subjected to thermal agitation, will acquire translatory movements, and these will inevitably set up atomic or molecular oscillations in virtue of the strong magnetic ties between one and another. The Weber element will be constrained to partake of these vibratory movements, and the substance as a whole will appear to lose magnetism and to gain in specific heat as the atoms or molecules successively take up vibrations with rise of temperature.

The model affords an explanation of the experiment mentioned above in which an alternating field applied to a ferromagnetic lowers its critical temperature, but leaves the temperature of the discontinuity of the specific heat unchanged. Such an alternating field would facilitate the vibrations of the Weber element, but would have no influence on the system of 'fixed' atomic magnets. Rupturing of atomic ties with accompanying loss of potential energy due to violent thermal agitation would account for the discontinuity of the specific heat.

That this model of the ferromagnetic atom should offer a plausible view of how an immense intrinsic magnetic field may exist in a magnet and yet not be influenced by external magnetic forces, and how the magnetism and specific heat of a ferromagnetic may be linked together, is the more noteworthy when it is remembered that the model was devised for an entirely different purpose, namely, the removal of a difficulty occurring in the early stages of magnetic induction with which the older and simpler model was confronted and was incompetent to meet.

Homo sapiens and African Prehistory.

The confirmation by Dr. Leakey and Mr. Hopwood of the antiquity of Hans Reck's Oldaway man, and Mr. Reid Moir's letter in Nature of Nov. 7, encourage me to publish, for the first time, a disconcerting discovery made in Uganda about a year ago.

At Nsongegi, in Ankole, the Kagera river is flanked by some remarkably fine terraces of which there are three. The upper and oldest is represented by mere remnants and carries in its upper parts an industry which, though not yet fully studied, is clearly seen to display marked Clactonian affinities, and is dated as Pluvial I. (Leakey's Kamasian). The second, or the hundred foot terrace, like the first, marks a time when in consequence of high precipitation the lakes rose and flooded back into their feeder valleys, and is dated as Pluvial II. (Leakey's Gamblian). Pluvial II. had, it would appear, two rainfall peaks, and during the relatively short period between them lake levels subsided to some extent, and thereby alluvial deposits in the valleys were exposed and became fertile plains, the hunting ground of prehistoric man. This interregnum was sufficiently long to permit of a moderate amount of denudation, and for the freshly exposed land surface to become more or less lateritised before it was again covered by gravels and silts. The temporary land surface yields stone tools, cores, and flakes in amazing abundance, representative of what in Europe would be regarded as two cultures: one of very late Acheulean and the other of early Mousterian facies, and it may be noted in passing that cleavers and some peculiar cores are of common occurrence. It would seem that a somewhat similar culture (the Nanyukian) of unproved but supposedly Interpluvial I. date (that is, between the Kamasian and the Gamblian) has been discovered in Kenya.

A number of pits were put down under my direction through the second terrace just referred to, and in one of them there was discovered *in situ*, 16 feet below the old occupation site that yields so many artefacts, a 'digging-stone', the usual large, round, flattish stone with a hole pierced through the middle. It was made from a comparatively soft rock (phyllite). Others have, I understand, been found resting on bed rock some 6 feet from the surface on the neighbouring hillsides. The specimen in question was found in well-bedded and quite undisturbed deposits belonging (unless our interpretation is radically wrong) to the earlier part of Pluvial II. times which, according to the Glacio-pluvial correlation, would belong to Riss days. The discovery was so disturbing that, beyond recording the facts in private letters, I forbore to give it wider publication pending further research. This will be carried out next year.

The discovery is not quite unique, however, for in 1926, Mr. T. Hirst, of the Geological Survey of Uganda, discovered a broken digging-stone stone at a depth of 3 feet from the surface in undisturbed deposits of a gravel apron connecting the 50-foot terrace of the Kafu river in Bunyoro with the river-flat deposits, both of which are interpreted as of Pluvial II. date, the latter being brought in by secular disturbances in Pluvial II. times. This inconvenient discovery appears to have been set aside and overlooked, and was only brought to light again when the corroborative evidence of the digging-stone of Nsongegi was produced.

Digging-stones have been regarded as of late appearance, but I have some which almost certainly date back to the dry period following Pluvial II. and preceding the Makalian Pluvial (presumably of Bühl date) of Kenya. They have not hitherto been found apart from the work of neanthropic man, and the two discoveries cited above strongly suggest that neanthropic man was in existence in the early part of Pluvial II. days, a possibility which, as I have said, I have hesitated to indicate. There is, however, less objection to it now that Reck's claim has been re-examined and upheld. E. J. WAYLAND.

Organisation of Scientific Abstracting Services.

As chairman of a small committee entrusted with the task of surveying the methods employed in scientific and technical abstract services, I invite the co-operation of editors and intelligence officers in collecting a body of information from which suggestions leading to increased efficiency may be derived. A conference recently held at the invitation of Mr. H. T. Tizard, president of the Association of Special Libraries and Information Bureaux, was attended by representatives of a large number of such services. Consideration was given, *inter alia*, to methods of dealing with foreign publications; this is one of the subjects in which information is sought, but the opportunity is being taken to gather confidential statements of fact and opinion which will form the basis of a comprehensive report on this most essential contribution to scientific progress. Responsible officers of organisations of the character indicated are invited to complete a questionnaire which has already been dispatched, or will be forwarded on receipt of a post-card, by Mr. S. S. Bullock, general secretary of the Association of Special Libraries and Information Bureaux, 16 Russell Square, London, W.C.1.

Gravity Anomalies.

IN India, Hayford gravity anomalies are unsatisfactory. The large negative and positive anomalies that are found cannot be ascribed to purely local density anomalies in the superficial crustal layer.

As a result of a somewhat lengthy investigation of these gravity anomalies, I have come to the conclusion that the Hayford hypothesis of isostatic compensation is incorrect, and that gravity anomalies can be adequately explained by a warping up and down of the crustal layers. According to this hypothesis, the main gravity anomalies, after removing topographical effects without compensation, are due to departures of the granite - tachylyte and tachylyte - dunite interfaces from their normal levels. The Airy system of compensation applies to folded sedimentary ranges under which there has been a deep down warp of the crustal layers, but horst ranges and other positive elements of the crust are entirely uncompensated.

Although these conclusions have been mainly derived from observations made in India, there appears to be good evidence that gravity anomalies, outside India in both continental and oceanic areas, can be successfully explained by crustal warpings without compensation. In particular, this hypothesis appears necessary to account for the remarkable anomalies found by Dr. Vening Meinesz in the East Indian Archipelago.

A paper describing these investigations will be published shortly as one of the Professional Papers of the Survey of India. E. A. GLENNIE.

Rotatory Magnetic Polarisation.

H. BECQUEREL[1] a énoncé le résultat suivant :

Pour les corps d'une même famille chimique le quotient de la rotation magnétique du plan de polarisation de la lumière Λ par le produit $n^2(n^2-1)$, n désignant l'indice de réfraction, est un nombre qui varie peu.

J'ai montré[2] que ce quotient $\frac{\Lambda}{n^2(n^2-1)}$ variait avec la température pour l'eau de 0° à 100° et pour le sulfure de carbone de 0° à 40°.

Il m'a semblé intéressant de faire la même étude pour le β méthylnaphtalène, dont Constantin Salceanu[3] a mesuré récemment la constante de Verdet et l'indice de réfraction à l'état fondu à six températures comprises entre 34° et 174°. Le tableau suivant montre que l'expression calculée augmente considérablement avec la température.

Températures.	n.	$\Lambda \times 10^5$.	$\frac{\Lambda}{n^2(n^2-1)} \times 10^5$.
34°	1·6056	4512	1109
78·5°	1·5864	4359	1142
111·7°	1·5695	4187	1162
142·5°	1·551	4039	1194
174°	1·5286	3879	1242

Superconductivity at High Frequencies.

WE have recently repeated with unsilvered vacuum flasks our experiments reported in NATURE of Aug. 29, p. 373, and in the *Phil. Mag.* of September last, and find lead and tin become superconducting with currents having frequencies of the order of 10^7 per second. We also find that the transition temperatures are progressively lowered as the frequency is increased.

Research Items.

Indian Archæology in Eastern Canada.—At the time of settlement of Eastern Canada by the French in the sixteenth and seventeenth centuries, the country was inhabited by tribes who spoke entirely different languages—Algonkian and Iroquoian. Algonkian sites are located on the banks of streams and lakes, usually on the north and west, and avoid clay. The Iroquoian sites of the semi-permanent villages in many cases are on the tops of flat-topped peninsula-like sand hills, the surrounding land being suitable for corn and other vegetable foods. The characteristics of the Algonkian and Iroquoian cultures are differentiated by Mr. W. J. Wintemberg in *Bulletin* 67 of the National Museum of Canada. The stone artefacts from both Algonkian and Iroquoian sites consist of chipped, ground, and polished implements, but the Algonkians were pre-eminent as stone-workers, and their artefacts of this material excel those of the Iroquois in number, variety, and uses. Stone pipes, indisputably of Algonkian origin, are not known on their sites, with the exception of the so-called 'Micmac' pipes, which are late. Iroquoian stone pipes are of many different types. Objects of native copper are found in many different localities, but in most cases not on sites yielding Algonkian pottery, those found here probably belonging to the mound-builders. Very few are found on Iroquoian sites, and then as a rule from those of the earlier periods. Earthenware from both classes of sites consists of fragments, a few whole pots and a few pipes. The bone work of pre-European Algonkians is poor; but the Iroquois were highly skilled bone-workers, and no artefacts are more abundant on their sites than those made of bone.

The Impaling Instinct of Shrikes.—In his systematic revision of the American shrikes (*Lanius*) Alden H. Miller includes many notes upon habits and behaviour, but we refer particularly to his observations upon the characteristic habit of impaling food (*Univ. California Pub. Zool.*, vol. 38, No. 2, p. 11, 1931). Young shrikes reared in cages, without the opportunity of learning methods of impaling, showed an initial inherited reaction fairly complete on its first appearance. It consisted, at its simplest, of the dragging of food along a perch until it met some resisting object (in this case nails inserted in the perch), when a series of tugs often lodged the food firmly on the projection. The object is to afford suitable fixation for rather large food objects so that they may be more readily torn to pieces. Small objects were eaten without any attempt at impaling. There was no indication that objects were impaled with the object of forming a store of food for future use, although there was evidence that even caged birds killed more than they could eat and kept on impaling surplus animals which they never touched again. Such actions are interpreted as automatic reactions to moving prey, an incomplete series of the ordinary feeding reactions; but it would be wrong to attribute them to a 'lust for slaughter' or to deliberate cruelty, since they appear to be purely instinctive. Indeed, contrary to popular opinion, shrikes usually kill their food thoroughly before impaling it.

Development of the Egg.—The attention of teachers and students of zoology is directed to a symposium on the development of the egg given at the Carnegie Institution, Washington, in November 1930 and published in three parts in the *Scientific Monthly* for June, July, and August 1931. In the first part, Dr. G. L. Streeter gives an account of the development of the egg as seen by the embryologist, based chiefly on the study of mammalian eggs. He traces briefly the development of the egg, for example, of the rabbit, gives a rapid summary of human development from the blastocyst stage, and adds some remarks on the importance of the quality of the egg: "Good eggs produce hardy, long-lived individuals and poor eggs succumb during intra-uterine life, infancy, or early years of maturity". Dr. Carl G. Hartman discusses the development of the egg as seen by the physiologist, follows the fortunes of the egg as it reacts with the ovaries and the anterior lobe of the pituitary, and considers the conditions produced by it during its sojourn in the mother's body, including the interplay of some of the endocrines. In the third article, Dr. C. W. Metz takes the geneticist's view of the developing egg and refers principally to the chromosomes and their influence in heredity and development. All three articles are well illustrated, and the first is particularly noteworthy for the photomicrographs of living mammalian eggs which form two of the full-page illustrations. One of these full pages contains eleven photomicrographs reproduced from Dr. P. W. Gregory's memoir on the early stages of the rabbit's egg; the other shows photographs, by Prof. Warren H. Lewis and others, of the eggs of the mouse, guinea-pig, monkey, etc. Three eggs of the mouse are shown in the two-cell stage (with polar body), and in the next figure ten eggs of the mouse are seen in the later cleavage, about the eight-cell stage.

Size-inheritance in Poultry.—An extensive study of the weight of fowls in crosses between Leghorns and Brahmas has been made by Mr. Wilson T. Waters (*Rhode Island Agr. Expt. Station Bull.* 228). Nearly 3000 birds were studied in experiments extending over ten years. Records of growth in weight were made, including the $F_1 - F_4$ generations, as well as back crosses and controls. Both breeds reach their full size in ten months. The reciprocal F_1 hybrids were intermediate in weight at the end of ten months. After the third week, Brahma chicks grow more rapidly than Leghorns, and thus attain a larger size. The F_1 and F_2 hybrids follow the growth curve of the Brahmas up to the seventh month, and the growth rate then becomes intermediate. Hybrid vigour is thus shown only in the earlier months of development of the hybrids. Segregation for size was shown in the F_2 and later generations. It is concluded that the difference in weight between the two breeds depends chiefly on two independent genes, each of which affects the weight equally, and they are cumulative in their effects.

Cellular Permeability.—Marcel V. L. Homes (*Bull. de l'Acad. Roy. de Belgique, Classe des Sciences*, 17, 3, 409–419; 1931) states that the absorption of solutes by living cells may be represented by an equation of the form $Q_t^e = Ae^{-at} + B$, where Q_t^e is the total quantity of the dissolved solute outside the cells at time t, and A, B, and a are constants. A and B may be evaluated in terms of the initial and equilibrium values of Q. It is shown that the constant a has dimensions $\frac{1}{[T]}$ and it is called by the author, who regards it as an important index of cellular permeability, the 'rate factor'. The rate factor may be experimentally determined in terms of the concentration of the external solution at equilibrium, at any time t, and at zero time, and in one case quoted is shown to be approximately constant. The actual rate of absorption at any time t, namely, dQ/dt, is simply derived from the value of the constant a and the initial and equilibrium values of Q. The permeability of a cell for a given solute is regarded as defined by two quantities: (1) the accumulation factor at equilibrium (as used by Hoagland and Davis), (2) the rate factor (*a*), which is expressed in the units reciprocal hours.

Adobe Brick Analysis for Plant Contents.—Exact knowledge regarding the early introduction of crop and weed plants into America is somewhat meagre, and the method of adobe brick analysis adopted by G. W. Hendry is yielding much valuable information, some account of which is given in *Agricultural History*, vol. 5, 1931. Adobe or sun-dried bricks readily disintegrate in water and yield their plant contents in a good state of preservation. The material so far collected has been small, but examination of the walls of various historic buildings has already thrown much light on the question of plant introduction. As regards crop plants, the wheats afford a good example of the importance of the discoveries made by this method. Propo wheat has been found in twelve out of fourteen buildings examined, the date of foundation of the earliest of which is given as 1701, and appears to have been the most extensively grown variety during the Spanish and Mexican periods. The introduction of this variety into California had, however, previously been thought to have been so late as 1870. Similarly, Little Club Wheat, usually considered as introduced from Chile about 1860, is shown to have been abundant in California, Arizona, and Sonora about a century earlier, thus assigning its introduction to the agency of Spanish missionaries from Mexico. New evidence is also provided regarding the introduction into California of alien weeds. Three species only, *Rumex crispus*, *Erodium circutarium*, *Sonchus asper*, all of which have a wide distribution, appear to belong to the pre-missionary period, namely, before 1769, and the writer regards them as probably present at the time of occupancy by Europeans. Other species are found particularly associated with the missionary period (1769–1824), while a further group would seem to be of definitely later introduction. Further studies of material collected from areas extending southward into Mexico would greatly extend the discoveries already obtained.

The Macdonnell Ranges.—The Macdonnell Ranges in Central Australia are relatively little known and are poorly mapped. Mr. C. T. Madigan describes the results of three expeditions to these ranges in the *Geographical Journal* for November. The whole area appears to be a series of eroded folds with east and west axes. The ranges are limbs of folds near anticlinal axes and the plains are filled synclinal troughs. The main range is described as an ancient geosyncline which has been above the sea since early Palæozoic times. The country to the south was invaded by Permo-Carboniferous and Cretaceous seas carrying icebergs, but the old ranges remained dry land. In later Palæozoic times isostatic adjustments to the results of erosion took place and the formations to the south were buckled. This buckling possibly continued into Tertiary times. To the north of the range the strata appear to have been practically undisturbed since Cambrian times. Mr. Madigan notes that the rivers with their southernly flow cut at right angles across the ridges and are excellent examples of antecedent rivers. The paper is illustrated by some striking photographs.

Pre-Cambrian Rocks of Quebec.—*Memoir* 166 of the Geological Survey of Canada (pp. 314 and geological map, 1931), by H. C. Cooke, W. F. James, and J. B. Mawdsley is devoted to a district in Quebec lying just east of the Ontario boundary. The main topics discussed are the Keewatin and Timiskaming series; pre-Huronian technics and intrusives; the Cobalt series; and the economic geology (sulphide deposits and gold and molybdenum deposits). The Keewatin series was here formerly called the Abitibi volcanics, but doubt as to the proper correlation has now been removed by continuous mapping from Ontario into Quebec. The internal structures of the Keewatin are described in precise and significant detail, and the observations are applied in interpreting the folding structures. Convincing evidence is given that the Timiskaming series of sediments is later than the Keewatin. Generally the discordance is slight, but in places the contacts suggest that highly-folded Keewatin lavas have been overthrust by sheets of Timiskaming formations. The intrusives include diorite-porphyry and amphibolite (earlier than the post-Timiskaming folding) and a gabbro-diorite-granodiorite-granite series (later than the folding). There are also many altered peridotites of which the age relationships are imperfectly known.

The Radioactive Constants.—The September number of the *Journal de Physique* contains the report, which also appears in the *Philosophical Magazine* and elsewhere, of an international committee which was appointed to decide upon the best values of the radioactive constants. Whilst largely devoted to tables of numerical data, it also contains some interesting comments on these. The value chosen for the number of α-particles emitted per second by a gram of radium is $3\cdot7\times10^{10}$. This is rather higher than the mean of older values, but is departed from to only a small extent by several apparently reliable recent determinations. For the uranium-radium ratio in old minerals the value $2\cdot94\times10^{6}$ has been adopted. In the matter of standard ranges of particles, certain discrepancies are noted, which perhaps throw doubt upon the accuracy of the useful relation which states that the range of an α-particle is proportional to the cube of its speed, and the report again emphasises that the use of a coefficient of absorption for β-particles, in the sense of the modulus of an exponential expression, is, although convenient, somewhat indefinite.

The Diffraction of Proton Waves.—An electrical investigation establishing the wave nature of protons of medium speed is described by Y. Sugiura in a *Scientific Paper* (No. 310) from the Tokyo Institute of Physical and Chemical Research. The method used was closely similar to one which has been used for electrons. A beam of protons was rendered homogeneous by sorting in a magnetic field, and was made to impinge upon a film of metal deposited on glass; diffraction took place at the metal crystals, and the pencils passing off were detected by an electrometer device. An electrically heated palladium tube, exposed externally to hydrogen gas, was used both as the source of hydrogen for the inside of the apparatus, and as the anode for the discharge system for accelerating the protons to the desired speeds. This proved very satisfactory, giving many more charged atoms of hydrogen than charged molecules. The wave-lengths concerned were of the order of a few hundredths of an angstrom unit, and the diffraction patterns obtained, although not very well resolved, were those which would be expected from the crystal structure as found by X-rays for the metals used.

Gallnuts as a Chemical Reagent.—In a paper in *Isis* for November, Dr. M. Nierenstein discusses the history of the use of gallnuts as a reagent. Pliny states that the black colour produced on paper soaked in extract of galls will serve to detect iron in verdigris. Although many ancient authors wrote on ‘atramentum’, no attention seems to have been paid to the phenomenon until Albertus Magnus referred to it in his botanical writings. Paracelsus describes the use of galls in detecting iron in water. Tachenius was mainly interested in the astringent principle present in the gall, and may be regarded as the founder of the chemistry of the tannins. Since alkalis react with vitriol, Tachenius regarded tannin as an alkali. A lengthy extract from this author is given, and also one from Boyle, on the use of galls in water analysis. The further references to the use of the reagent in testing for iron are more briefly discussed.

Isolation of the Radical Ethyl.—Two years ago Prof. Paneth and Herr Hofeditz of Königsberg succeeded in demonstrating the somewhat transitory existence of the radical methyl in the free state (Nature, **124**, 161, July 27, 1929). In the November issue of the *Berichte der deutschen chemischen Gesellschaft*, Prof. Paneth and Herr Lautsch describe further experiments which have resulted in the isolation of the radical ethyl by a method which differs only slightly in detail from that used in preparing methyl. Thus the lead tetra-ethyl was vaporised at - 25° C. instead of at - 70° C., and since it dissociates at a lower temperature than lead tetramethyl it was possible to substitute hard glass for quartz. The gaseous product obtained in these experiments resembled methyl somewhat closely, so that its identity had to be established. This was done by bringing it into contact with zinc, with which it reacted to form a compound which had the same melting and boiling points as zinc ethyl. Further proof was obtained when the zinc ethyl was oxidised to zinc oxide and ethyl alcohol, the existence of the latter being established by means of the iodoform reaction. The ethyl also combined with antimony to give antimony triethyl. Attempts to isolate the *n*-propyl and isobutyl radicals have not yet been successful, since these more complex products show a tendency to break down. In discussing the mechanism of the reaction involved in the disappearance of the free radicals, the authors come to the conclusion that the latter process takes place on the walls of the containing vessel and is unimolecular. They have also shown that the main product in this case is *n*-butane, which was also identified, but they did not succeed in obtaining ethane from methyl.

Portable X-Ray Medical Unit.—We have received *Bulletin* A2 from Messrs. Watson and Sons (Electro-Medical), Ltd., describing the Watson-Sankey Portable X-ray Unit, which has been designed in collaboration with Dr. R. H. Sankey. The component parts consist of a trolley base on which the apparatus is mounted, a switch board, a high-tension transformer, and a tube stand. These components are small and light, making for easy transport, and fit comfortably into dust-proof canvas cases. They can be assembled within a few minutes. It would appear to be an advantage that the apparatus can be operated on the ordinary power supply or, if necessary, on the lighting circuit. The price of the outfit is about £160, including one Metalix Radiator X-ray tube.

Astronomical Topics.

The Leonid Meteors.—The observations made in Iowa in the early hours of Nov. 16 have already been noticed (Nature, Dec. 5, p. 972). A Science Service Bulletin of Nov. 19 reports that a richer shower was seen on the morning of Nov. 17. Dr. Olivier observed from the Catskill Mountains, where the weather was perfect. Fully 900 meteors were seen here, including some fine fireballs; two of these left trains that lasted for 12 minutes each. He states that he saw more meteors this year than in 1901, which was the best display at the last visit of the rich part of the swarm. The richest half-hour was from 3.30 to 4 a.m. (add 5 hours to reduce to U.T.). Mr. A. M. Skellett observed the effect of the meteors on the transmission of wireless waves: he says, "A cloud of electrified particles accompanies every meteor in its descent. When the meteor enters the Kennelly-Heaviside conducting layer this disturbs the condition of balance, so that the effective height of the layer is temporarily lowered. A fogging of radio-signals results." This is a point that should be examined if the expected rich shower occurs next November.

Mohd. A. R. Khan, principal of the Osmania University College, Hyderabad, Deccan, writes that he observed twelve Leonids on Nov. 15, between 22^h 10^m and 23^h (Greenwich Time). Of these, the eighth was conspicuously bright. The sky was cloudy during the nights of Nov. 13 and 14, while Leo was above the horizon.

Sir William Herschel's Mirrors.—Capt. M. A. Ainslie has recently acquired two mirrors made by Sir W. Herschel; it is highly probable that one of them is the actual mirror that was in use when the planet Uranus was discovered. They are of seven-inch aperture and seven-foot focus. The two mirrors are exactly alike in these respects, and Capt. Ainslie notes that they were probably used in an attempt that was made to use them together in a binocular telescope; by placing the flats at different distances from the mirrors, it is possible to form the images at a distance apart equal to the distance between the eyes. Capt. Ainslie has had the mirrors mounted, and tested them carefully on double stars and other test objects. He gave an account of his observations at the meeting of the British Astronomical Association on Nov. 25. The reflecting power of the mirrors is not very good; it has doubtless deteriorated; but the quality of the images is astonishingly good, and some very close double stars could be separated. He observed the planet Uranus, and noted that a power of 200 showed clearly that it had a disc.

The Velocities of Distant Nebulæ.—A re-examination of the increase of radial velocity with distance for the extra-galactic nebulæ has been made by Hubble and Humason in the *Astrophysical Journal*, vol. 74, p. 43. The main difficulty lies in determining the distances of these nebulæ, for which purpose various indirect methods have to be applied. For those nebulæ in which individual stars can be recognised, the presence of cepheids, novæ, and other suitable objects forms a valuable and fairly accurate guide; the cepheids being the most trustworthy data of all. Such nebulæ then form a sample collection from which the average total luminosity of a nebula may be determined. Individual luminosities are found to be closely grouped round this mean value, which may thus be used for estimating the distances of the more remote nebulæ. This is, in fact, the only method available for such bodies, some of which are estimated to be 32,000,000 parsecs distant. The velocity-distance relation has been re-determined with the aid of new material (including Shapley's revision of the luminosity-period relation for cepheids), and the authors express it in the form: velocity = distance/1790, with an uncertainty of about ten per cent.

A paper by Humason in the same journal, p. 35, gives the results of radial velocity measurements for forty-six extra-galactic nebulæ as observed at the Mount Wilson Observatory. The largest observed velocity was 19,700 km./sec., and the observations (with one exception) confirm the velocity-distance correlation.

Scientific Management Problems.

A SIGNIFICANT feature of the centenary meeting of the British Association was the inclusion for the first time of a department devoted to industrial co-operation in Section E (Economics). Whether or not, as Major L. Urwick suggested in opening a discussion on the aims, methods, and progress of research into management problems, the contrast between the control over natural resources with which science has endowed us and our lack of control over economic and social forces exemplified in the grave economic crisis has provided the stimulus, the application of scientific methods in this field is pregnant with possibilities. While the assertion that business is science or even a profession might be challenged by many who are well aware of the debt that industry owes to science, and who might even admit that the only hope of the survival of business is in its submission to the logic of scientific method, comparatively few would dispute the statement that the only hope of any control of economic forces lies in the application at every point in the business structure of the world as the final criteria governing its actions, of the logic and methods of inductive science by which those forces have been created.

The discussion opened by Major Urwick indicates that, by inviting industrial representatives to discuss industry from the scientific point of view, the British Association has recognised the integration of industry and science. Management research aims at bringing the whole volume of existing scientific knowledge and technique to assist in the solution of problems of planning, supervision, control, and legislation involved in economic operations. As pursued by the International Management Institute, such research is free from the grotesque and unintelligent forms which so-called research of this type can assume in the service department of American universities, a tendency from which, as Flexner has shown, even the Harvard School of Business Administration is not exempt. Major Urwick rightly pointed out that the research worker in management has little concern with popular differentiations between organisations on the ground either of objective or of ownership. The service to be rendered by science in this field must be disinterested and represent in the main attempts to enlarge the boundaries of an existing department of science or to apply scientific methods to discover general principles of management.

The rapid extension of this field of inquiry, especially in America, has led to two main difficulties which retard development. The first difficulty lies in the mass of published work, much of which has unfortunately been uncritical and even unscientific. This difficulty becomes less serious with the increasing number of managers who have received formal training and with the emergence of authoritative textbooks, but the serious difficulty presented by the absence of industrial co-operation is only slowly giving way before the formation of management research groups or the use of management ratios. Even yet we know practically nothing of the principles which should govern the large-scale combinations characteristic of modern business, and beyond this, traditional thinking and vested interests of all kinds oppose scientific reorganisation of the world economy. The increased power production conferred by science has been used by all kinds of groups—social, professional, national, or venal—to secure differential advantages; and revolutionary change or social chaos can only be avoided if we can achieve methods of organisation which will give us control of the forces released by a rapidly mechanised economy. The integration of science and business on lines initiated by the British Association may secure a new approach to the whole situation.

In describing the American position, Dr. H. S. Person, managing director of the Taylor Society, New York, remarked that very little management research was comparable with the scientific research carried out in laboratories, although in its best manifestations management research sought to substitute the control of knowledge for whim and casualism, and the possibility of developing the principles and technique for the control of our economic destiny had already been demonstrated. The present industrial difficulties in the United States may be connected with individualistic and imperfectly applied industrial research which creates problems of management. Discussing the research into methods of management which in the aggregate has transformed American management, Dr. Person emphasised its practical and pragmatic basis, the methods adopted and the extent of the inquiry being determined by the specific problem under investigation. Management research was also characterised by specific findings which made it vital and constructive, and despite its rapid expansion was still incomplete and was now tackling problems of collective government. The readiness of American industry to exchange information is due to the conviction that general improvement in management and general prosperity create an environment favourable to greater individual prosperity.

Sir Horace Wilson, discussing the British position, pointed out that management research differed from technical research in that progress was almost impossible in its main subjects except by co-operative methods. Training for industry was one aspect of management research which had attracted much attention in Great Britain, and the limitation of the training given in the Department of Business Administration at the London School of Economics to students of good general education who had had two years' practical experience in business indicated a method of avoiding some of the pitfalls of such training in America. Other problems with which management research was concerned were the recruitment of personnel both for administration and for shop management, and in addition there was little experience yet available to guide us in the management of large industrial units or to indicate the limits of effective control of such units. Management research should materially assist in discovering the principles to be observed in organising such units and in providing the men capable of managing them. Many institutions, such as the British Engineering Standards Association (now the British Standards Institution), the Industrial Welfare Society, and the National Institute of Industrial Psychology, had made important contributions to special management problems. The mutual exchange of experience in the solution of particular problems could never take the place of the proper selection of personnel for key positions, but over a wide field could improve and assist the practice of management.

Dr. Hellmuth Boller, describing the Austrian position, referred to the effect of foreign competition and the foreign market required for nearly sixty per cent of Austria's industrial output as well as the persistence of a steady fifteen to twenty per cent of unemployment in the working population in forcing on management research and efficiency. Under a

National Board, groups had been organised for the exchange of experience, covering the metal, textile, and foodstuffs industries. The importance of securing the full co-operation of employees had clearly been demonstrated, and the close and intensive co-operation secured between the groups of chiefs and of subordinates was an essential method of organising exchange of experience. Confidence and mutual interest were the only sound basis for management research, and particularly in the Austrian method of critical visits to selected departments combined with advance or preliminary reports which were afterwards elaborated. No objections had been raised to the publication of the findings of sub-groups of experts based on these reports, and particular attention had been paid to budgetary control.

The Lister Institute.

THE Report of the governing body of the Lister Institute for 1931 refers to the various changes which have occurred in the membership of the governing body, council, and members and staff of the Institute during the past year, and describes in brief the numerous researches in which the staff and their co-workers have been engaged. A bibliography is appended to the Report, to which those interested in particular subjects may be referred for the fuller information to be obtained from original papers. Among the changes in staff may be mentioned the retirement of Sir Charles Martin and Prof. A. Harden. Prof. J. C. G. Ledingham took up the directorship of the Institute and Dr. R. Robison succeeded Prof. Harden as head of the Biochemical Department on Jan. 1.

The researches described may be roughly classified into investigations in experimental pathology and bacteriology and studies on nutritional subjects. The National Collection of Type Cultures is housed at the Institute, although the salaries of the necessary staff are furnished by the Medical Research Council: during the year, more than 5000 strains of bacteria and fungi have been distributed to workers in various parts of the world, and 200 types, including many new species, have been added to the collection. A third and enlarged edition of the catalogue of the collection is in course of preparation.

Prof. Ledingham has found in his studies on fowl-pox that the Bollinger bodies seen in the epithelial cells of the lesion consist of agglomerations of Borrel bodies ($0{\cdot}25\mu$ diameter) in a lipoprotein matrix. The Borrel bodies pass through Berkefeld V filters and a single one can infect, so that it is possible that these minute bodies are the actual etiological agents. Dr. G. H. Eagles and Dr. D. McClean have been able to cultivate vaccinia virus in a cell-free kidney extract and carry through a series of subcultures. The virus survives for considerable periods under anaerobic conditions in the cold, but filtration of the centrifuged kidney extract removes some property essential to prolonged survival. The virus can be filtered through the Berkefeld V: as with fowlpox virus, it is probable that the elementary bodies found in the lesions are the actual infecting agents.

Dr. E. W. Hurst has confirmed the observation that the virus of poliomyelitis (infantile paralysis) is transmitted along the axis-cylinders of the nerves. Monkeys can be infected with regularity by combining intrasciatic inoculation of the virus with mild trauma to the nerve. Virus and lesions first appeared in the lumbar cord, the latter first on the side of the inoculated nerve: the leg area of the opposite motor cortex was the next site to harbour virus, other areas only being involved much later. The lumbar cord is connected chiefly with the opposite motor cortex: there are only few connexions with other parts of the central nervous system. With Dr. R. W. Fairbrother, Dr. Hurst has also shown that infection with vaccinia virus does not modify a simultaneous infection with poliomyelitis. Dr. Morgan has been able to immunise two out of four horses to poliomyelitis and obtain a potent anti-serum. The potency is precipitated with the euglobulin fraction of the serum protein by adding up to 34 per cent by volume of saturated ammonium sulphate solution: the precipitate can be dialysed and redissolved in normal saline, giving a concentrated preparation which should be of great advantage in the treatment of the disease by the intraspinal route. Contacts with cases of infantile paralysis have been found to possess antibodies in their serum, although they have not developed the disease.

Work has also been carried out on the preparation of gas gangrene antitoxin, on the preparation of a dysentery toxin (Shiga) for use as a test toxin, and on the preparation of toxic extracts of the meningococcus for the purpose of titrating anti-meningococcal sera. A concentrated anti-staphylococcus serum has also been produced by the immunisation of a horse with staphylococcal filtrates.

Some preliminary work has been carried out under the auspices of the Accessory Food Factors Committee on vitamin standards. Miss Hume and Miss H. Smith have been investigating the suitability of pure re-crystallised carotene as a standard for vitamin A; Dr. H. Chick and Miss H. M. Jackson, a concentrate adsorbed on kaolin from an extract of rice polishings, provided by Dr. Jansen, as a standard for vitamin B; and Dr. Zilva, decitrated lemon juice as a standard for vitamin C. Miss Hume, Miss Pickersgill, and Miss M. Gaffikin have been examining the standard solution of irradiated ergosterol issued by the Medical Research Council for use in the estimation of vitamin D. They find that it is stable when kept at 0° C. Data have also been collected on the accuracy of the biological test for vitamin D. Consistent results were obtained with ten animals on each dose, good results with six, but inconsistent results with only three or four on each dose. An attempt is being made to construct a curve relating dosage and degree of calcification.

Dr. H. Schütze and Dr. S. S. Zilva have established the existence of a very definitely lowered resistance to infection with *S. Suipestifer* among rats deprived of vitamin A, as compared with animals on a complete diet.

Dr. H. Chick and Miss Copping have found that vitamin B_2 is destroyed by strengths of alcohol above 50 per cent: its solubility and precipitation limits are uncertain and appear to depend on the compounds with which it may be associated in solution. Egg white is a convenient source of this vitamin since it contains no vitamin B_1. Active concentrates have been prepared by aqueous acid extraction, which cure the dermatitis developing in rats on a vitamin B_2-free diet, but do not stimulate growth for more than a few weeks. Autoclaved yeast extracts are, however, satisfactory. It thus appears that a third factor is required by the rat for growth in addition to vitamins B_1 and B_2. This factor is also present in green-leaf vegetables, egg-yolk, and ox-liver, but absent from wheat embryo, meat, and white vegetables. Its thermostability distinguishes it from the other B vitamins hitherto described. Miss Roscoe has found no relationship between fat in the diet and the need for vitamin B_2: fat lessens the need for vitamin B_1.

Dr. W. R. Aykroyd has found that the endosperms of wheat, rice, and maize contain little vitamin B_1 as compared with the embyro or whole grain. Parboiled rice, however, even after milling, contains definite amounts, due apparently to diffusion inwards from the germ and pericarp during the boiling. Maize has been found a good source of vitamin B_2, as good as wheat, and better than rice. Pellagra, however, occurs among maize-eating peoples and is rarely observed where rice is the staple food. This result is against the theory that pellagra is due to a simple deficiency of vitamin B_2.

Miss E. M. Hume and Miss H. H. Smith have compared the effect on bone calcification in rats of diets low and rich in ergosterol, the animals being given a complete synthetic diet without vitamin D but irradiated daily. The bone ash was slightly lower in the animals on the low ergosterol diet which were not irradiated than in any of the other groups. The diet used contained no fat: many of the rats developed scaliness of the tails, which has been attributed to absence of fat from the diet. Hume and Smith observed the condition, however, in other rats on a diet containing fat, so that it must be due to some other defect in the diet.

Dr. N. S. Lucas has reinvestigated the permeability of human epidermis to radiations between 4370 A. and 2400 A. The transparency has been much underestimated, since considerable scattering of the incident light occurs, so that it fails to reach the slit of the spectrograph, although it may ultimately be transmitted by the skin at a distance from its point of entry. When allowance is made for this, by producing scattering of the light before it reaches the skin, it is found that 55 per cent is transmitted at 3130 A. and 26 per cent at 2940 A. The absorption curve agrees closely with those of casein, serum albumin, tryptophane, and tyrosine.

Dr. Smedley-MacLean and Miss Pearce have shown that when a large excess of peroxide acts on oleic acid at 95° C., less than 20 per cent of the carbon appears as formic, carbonic, and acetic acids, acids with 15 and 12 carbon atoms being obtained, that is, oxidation occurs first at the double bond followed by oxidation of the 18 carbon chain in the γ position. In the presence of a cupric salt, the oxidation proceeds much further, 70 per cent appearing as the lower acids. At 60° C. the chief products are 4-keto 7-hydroxy caprylic and succinic acids with 20 per cent of the lower acids. The evidence lends no support to the view that fatty acids are broken down by β-oxidation in the body. The presence of succinic acid is of interest since an oxidising enzyme for this acid is widely distributed throughout the tissues.

Among other researches with which the Report deals may be mentioned those of Dr. Robison on calcification *in vitro* and on the chemistry of the hexosephosphates and the work of Dr. V. Korenchevsky on the amount of fat in castrated and cryptorchid animals: degeneration or removal of the seminiferous tissue leads to an increase in fat deposition.

A New Illumination Device for Microscopy.

THE microscopic examination of opaque materials and the surface structure of natural objects have recently attracted much attention. The root idea of the Lieberkühn has been embodied in various types of ring illuminator in which the light may reach an annular reflector from below, or may be dealt with in a manner more analogous to the vertical illuminator.

Messrs. Ernst Leitz have recently brought out improved apparatus of the latter kind in which the light reaches the object from an annular illuminator around the objective, but avoiding the restriction in the size of the object which has been necessary in some arrangements. A small 8-volt lamp and condenser project a roughly parallel beam which is reflected downwards by an annular mirror held at 45° to the beam and to the axis of the microscope tube. The reflector is pierced with a central aperture which transmits the upward image-forming rays from the objective. The annular beam thus produced from the reflector enters an annular lens (or reflector system for the higher powers) and is focused on the object without traversing the objective itself. Thus the disadvantages of back reflections and stray light are avoided. The general arrangement of the parts is shown in the accompanying illustration (Fig. 1).

A special series of fifteen new objectives, comprising 'dry', 'water immersion', and 'oil immersion' lenses has been produced, in which the low-power lenses are designed to work without a cover glass over the object. Each of the low-power lenses has its own ring condenser, and rapid transition from one object to another is facilitated by the use of a convenient objective changer which clamps firmly and definitely into position. The lamp and condenser system need not be changed.

One advantage of apparatus of this kind is that the illumination can be controlled with much greater precision than with any more or less haphazard reflector arrangement, and that a systematic study of objects can therefore be commenced with less uncertainty. The interpretation of the images in some cases, especially with the higher powers, is not an easy matter, and will require careful study; diffraction effects can easily be mistaken for surface colour; nevertheless, it is clear that new investigations are possible. The well-illustrated catalogue of this 'Ultropaque Illuminator' gives photographs of various objects, amongst which are vegetable tissues, skin, chromatophores, leather, wood-sections, fabrics, and so on. This method may also have important possibilities in metallography. L. C. M.

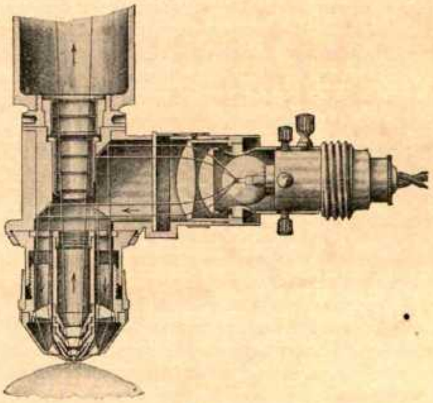

FIG. 1.

Mycorrhiza in Relation to Forestry.

IN Section K (Botany) at the recent meeting of the British Association, a report was read by Dr. M. C. Rayner on "Mycorrhiza in Relation to Forestry". The paper was drawn up by Dr. Rayner, and comprised the Report of the Committee (Mr. F. T. Brooks, Dr. Rayner, and Mr. W. H. Guillebaud), to which a grant of £40 had been made by the British Association to be spent in investigation work in this branch of research.

The purpose and scope of the investigations are explained in a preliminary statement printed in last year's British Association Report. In this statement the main objects of research are summarised as follows: (1) To ascertain whether the formation of normal mycorrhiza may fairly be regarded as a causative factor in the healthy growth of young trees, it being already assumed that it is an invariable concomitant of such growth. (2) To determine whether the absence of mycorrhiza associated with unsatisfactory growth is related to:

(*a*) Absence of the mycorrhiza-forming fungi appropriate to the trees; or

(*b*) the existence of soil conditions inimical to the formation of functional mycorrhiza of a beneficial type. (3) To ascertain whether it is practicable to supply deficiencies or ameliorate existing soil conditions by experimental treatment of nursery stock or in other ways.

The experiments carried out under (1) were made with Scots, maritime, and Corsican pines. Evidence for the first only is as yet available, but it appears to support the view that the formation of normal mycorrhiza is a causative factor of great importance to the growth of young trees. Under the second head, the presence or absence of the appropriate fungi, some interesting investigations have been carried out which in many cases require further work for substantiation upon a practical basis. The Wareham and Ringwood plantations formed the site of this research work, and under (3) it is stated that certain definite conclusions have been reached respecting the inimical causes operating in the Wareham plantations, and that experiments on the lines inaugurated will show that practical field methods at a reasonable cost can be undertaken to ameliorate the existing poor conditions.

The Report should be consulted for the details of this valuable piece of research, and it is to be hoped that funds will be available to continue it to a practical conclusion.

University and Educational Intelligence.

BIRMINGHAM.—The new ore-dressing laboratory of the Mining Department is to be opened on Dec. 16 by the Right Hon. Sir Robert Horne. At the degree congregation to be held on the same day, honorary degrees will be conferred on Sir Robert Horne and on Mr. Evan Williams, president of the Mining Association of Great Britain.

The Council is recommending to the Court of Governors that the title of emeritus professor be conferred on the former vice-president and professor of mechanical engineering, Prof. F. W. Burstall, and on the former professor of brewing and biochemistry, Prof. A. R. Ling.

The number of registered students for the current session shows a considerable increase, new entries being nearly nine per cent above those for 1930.

CAMBRIDGE.—Dr. H. C. Darby has been appointed University lecturer in geography.

The John Humphrey Plummer professorship of mathematical physics has been established. The stipend of the professor is £1200 a year or, if he holds a fellowship with dividend, £1000 a year. Candidates are requested to communicate with the vice-chancellor on or before Jan. 6. No testimonials or references need be sent. If a candidate desires to submit any, they should not exceed four in all, and in the case of testimonials, ten copies of each should be sent to the vice-chancellor not later than Jan. 6.

It has been recommended that the following sub-departments in the University shall be recognised: In the Department of Botany, the sub-departments of (1) Plant Physiology, (2) Mycology; in the Department of Zoology, the sub-departments of (1) Experimental Zoology, (2) Entomology. The directors of these sub-departments shall be the University readers in the subjects.

LONDON.—The following degrees have recently been conferred:—D.Sc. degree in chemistry on Thomas J. Drakeley (University College) for a thesis entitled "The Reactivity of Coke" (*Jour. Soc. Chem. Ind.*, Aug. 1931). D.Sc. degree in geology on Leo Picard (Imperial College—Royal College of Science) for a thesis entitled "Geological Researches in the Judean Desert" (obtainable from Max Weg, Leipzig). D.Sc. degree in physical chemistry on Frederick K. V. Koch (Imperial College—Royal College of Science) for a thesis entitled "On Ionic-Molecular Interaction" (*Jour. Chem. Soc.*, 1927–28, 1930–31; *Phil. Mag.* 1930–31). D.Sc. degree in zoology on Marjorie J. Triffitt (Bedford College) for a thesis entitled "Studies on *Heterodera Schachtii*" (*Jour. of Helminthology*, 1928–31; Imp. Bureau of Agric. Parasitology Bulletin). D.Sc. degree in chemistry on Terence T. H. Verschoyle (Imperial College—Royal College of Science) for a thesis entitled "The Ternary System Carbon Monoxide-Nitrogen-Hydrogen and the Component Binary Systems between Temperatures of − 185° and − 215° C., and between Pressures of 0 and 225 Atmospheres"; with two subsidiary contributions.

AN election to Beit fellowships for scientific research, founded and endowed by the late Sir Otto Beit, and tenable at the Imperial College of Science and Technology, South Kensington, will take place on or about July 12, 1932. The annual value of a fellowship is £250, and it is tenable for two years. Candidates must not hold any other scholarship or fellowship. Not more than three fellowships will be awarded in 1932. Applications must reach the Rector, Imperial College, South Kensington, London, S.W.7, from whom further information and forms of application may be obtained, not later than April 12, 1932.

THE thirty-second annual meeting of the Science Masters' Association will be held on Dec. 29–Jan. 1, at the Chemistry Department, Imperial College of Science, South Kensington, S.W.7. The president, Dr. Cyril Norwood, will deliver his presidential address on Dec. 29. Lectures will be given by Prof. Jocelyn Thorpe, on schools and research, Dr. G. C. Simpson, on modern weather forecasting, and Prof. E. W. MacBride, on the inheritance of acquired characteristics. Several discussions have been arranged, amongst which is a consideration of the size of classes for practical work in science. Amongst the lecture-demonstrations which will be given are those on experiments in colour, by Mr. E. G. Savage, and on television suitable for school laboratory work, by the Television Society. In connexion with the meeting, several visits of interest, and members', trade, and publishers' exhibitions have been arranged.

Birthdays and Research Centres.

Dec. 13, 1874.—Prof. R. S. Troup, C.I.E., F.R.S., professor of forestry in the University of Oxford and Director of the Imperial Forestry Institute, Oxford.

Among the many important problems affecting the British Empire at the present time there are few which afford more scope for useful investigation than the question of co-ordinated surveys dealing with vegetation and soil in relation to climate on one hand and biotic factors on the other, with a view to the recognition of the climax types which may occur and a survey of their distribution. Such surveys would place the economic use of the land on a more scientific basis than is the case at present, since they would indicate the trend of natural processes on distinct soils and sites, and would tend to prevent the policy and practice of agriculture and forestry from running counter to natural laws. The effect of clearing forest in causing the rapid deterioration of the soil opens up a large subject of investigation in different parts of the Empire.

Dec. 16, 1859.—Prof. D. H. Campbell, professor of botany in Stanford University, California.

There is great need for a classification of the archegoniates and spermatophytes more in accord with our present knowledge than is the very antiquated system employed by many taxonomists both in Great Britain and the United States. Too often taxonomists are more interested in the discovery of new species and in questions of nomenclature than in a comprehensive study of the relationships of the major plant groups.

The importance of the genetic problems, which have attracted so large a number of botanists at the present time, is unquestionable, and our knowledge of the mechanics of heredity has been greatly advanced. However, this absorption in the *methods* of evolution has directed attention from important problems dealing with the history of the plant kingdom, and we must still depend mainly upon comparative morphology, ontogeny, and the fossil record for an understanding of the course of evolution in the higher plants.

Dec. 16, 1884.—Prof. J. W. Bews, professor of botany in the Natal University College, Pietermaritzburg.

The study of South African plant ecology and plant geography continues to yield interesting results, which have an important bearing on the larger question of the evolutionary history and differentiation of the flowering plants as a whole. I am still directing my attention to these problems, from both the morphological and physiological sides. Detailed studies of other families (besides the grasses already dealt with) are being undertaken, while comparative physiological work on the water-relationships and carbohydrate metabolism of more and of less highly evolved types of plant is also being carried out with the help of students. As a further development, I am becoming interested in the study of ' human ecology '.

Dec. 17, 1861.—Mr. Edward Heron-Allen, F.R.S., hon. mem. R. Accad. S. Caecilia, Rome, past president of the Royal Microscopical Society.

My seventieth birthday finds me with my collaborator, Mr. Arthur Earland, in the middle of Part 2 of our monograph of the " Foraminifera of the *Discovery* Expedition ". When the whole of this work is finished we hope to deal with those of the Great Barrier Reef Expedition. My monograph of the " Recent Foraminifera of Great Britain ", which is kept up to date, must wait for publication (which is provided for) until after my death. Our collections and library will shortly be concentrated in a room placed at our disposal at the Natural History Museum, and their rearrangement and the keeping of them up to date, catalogued and indexed, will occupy all my ' idle ' hours for the rest of my life.

Dec. 17, 1882.—Mr. F. T. Brooks, F.R.S., reader in mycology in the University of Cambridge.

I am especially concerned at present with the problems of disease resistance in plants, particularly with those relating to parasitic invasion. These problems are of great botanical interest, and they are also of considerable economic importance. The interplay of host, parasite, and environment is an intriguing study.

Dec. 18, 1856.—Sir J. J. Thomson, O.M., F.R.S., Master of Trinity College, Cambridge, and formerly Cavendish professor of experimental physics in the University of Cambridge.

Experimental researches on problems relating to the discharge of electricity through gases, and the preparation, in collaboration with my son, Prof. G. P. Thomson, of the second volume of " Conduction of Electricity through Gases ". Theoretical investigations on the use of lines of electric force to give a physical representation of the processes going on in the electromagnetic field, including the phenomena associated with electronic waves.

Societies and Academies.

LONDON.

Geological Society, Nov. 27.—A. C. Seward: (1) Fossil plants from the Bokkeveld and Witteberg beds of South Africa. With a few exceptions the specimens are referred to a single genus, for which a new generic name is proposed. The fossils are portions of stems of a plant allied to some of the psilophytalean genera characteristic of Middle Devonian rocks in Europe. They bear a close resemblance to stems of *Cyclostigma*, but there are grounds for regarding the South African plant as rather more primitive than any of the arborescent Lycopodiales, and probably more closely related to the Psilophytales.—(2) Carboniferous plants from Sinai. In 1868 Salter briefly described a specimen from the Sinai Peninsula as *Lepidodendron mosaicum*: this name is adopted for the best specimens in this collection, and others are named *Lepidodendron sp.* and *Halonia tortuosa*. *Lepidodendron mosaicum* Salter is compared with *L. obovatum* Sternberg and with other species. The age of the Sinai beds as indicated by the plants would seem to be either near the upper limit of the Lower Carboniferous, or possibly early Westphalian. A brief reference is made to phytogeographical problems raised by the occurrence of Carboniferous plants to the south of the Tethys Sea.—T. N. George: The British Carboniferous reticulate Spiriferidæ. The short-hinged spirifers which are customarily referred to the genus *Reticularia* fall into two main groups. One group, constituting *Reticularia* proper (genotype *Terebratula imbricata* Sowerby), is characterised by relatively large forms which possess a coarse shell-structure and an apparent absence of biramous spines. The second group, referred to a new genus, contains relatively small forms with a fine shell-structure which do not advance beyond an incipiently uniplicate stage in the development of shell-sculpture.

Dublin.

Royal Irish Academy, Nov. 9.—**R. K. Boylan**: The mobilities of atmospheric large ions. Observations made by the McClelland method and also by the Zeleny divided-electrode method disclose the existence in atmospheric air not only of the Langevin ions of mobility 0·0003 cm./sec./volt./cm., but also of groups of large ions of higher and lower mobilities.—**R. Southern** and **A. C. Gardiner**: Reports from the Limnological Laboratory (2). The diurnal migrations of the Crustacea of the plankton in Lough Derg. Continuous observations on the vertical distribution of seven species of Crustacea of the plankton were made during the day and night for a period of six days from a boat anchored in the middle of Lough Derg. The daily migrations of the plankton are shown in a series of twenty histograms. Considerable variation in distribution was shown from day to day, and the causes of this variation are investigated. Certain species are composed of classes differing in their behaviour. The migrations of adult *Daphnia longispina* are precisely reversed in the case of immature forms of the same species. The males of *Cyclops strenuus* remain in deep water throughout the day and night, whilst the females and immature individuals migrate to the surface at night.

Paris.

Academy of Sciences, Nov. 3.—The president announced the death of Gabriel Kœnigs, member of the section of mechanics.—**C. Gutton** and **G. Beauvais**: Oscillators with very short waves. An experimental study of the effects of gas pressure in a valve producing short waves. For very low pressures, some hundred thousandths of a millimetre, the oscillation frequencies depend on the real frequency of the oscillating circuit. With higher pressures in the valve (0·008 mm.) a higher frequency is obtained, which is determined by the dimensions and potentials of the valve electrodes.—**Alessandro Terracini**: The reducibility of certain algebraical correspondences.—**F. Leja**: The convergence factor of series of polynomials.—**D. Belorizky**: The solution of the problem of three bodies given by Sundmann.—**Mlle. Suzanne Veil**: The diffusion and cataphoresis of methylene blue in gelatin. An application of the microphotometer to the problem. The curve of diffusion is regular and gives no evidence of the discontinuity noted by Mokruschin. The phenomenon of cataphoresis of methylene blue in gelatin is much more complex than that of diffusion.—**J. Hérenguel** and **G. Chaudron**: The preparation of pure magnesium by sublimation. The apparatus used is described and figured. After two sublimations in a high vacuum (mercury vapour pump) the magnesium contained less than 0·001 per cent of chlorine and was free from silicon and iron. The metal was fused to an ingot in the same apparatus in argon under a pressure of some centimetres.—**D. Ivanoff**: The mechanism of the reaction between ethyl carbonate and the Grignard reagent.—**L. Hackspill**, **A. Stieber**, and **R. Hocart**: Crystallised boron. It is shown that the substance sold as crystallised boron consists mainly of compounds of this element. The authors have prepared a boron of 99 per cent purity by the action of a high frequency discharge in a mixture of hydrogen and boron trichloride. Pure boron can also be obtained by the action of an incandescent tungsten filament on the vapour of boron tribromide. Both these give the same X-ray spectrum.—**Bogdan Varitchak**: The movements of the protoplasm in an Ascomycete, *Sordaria fimicola*.—**Raymond Hovasse**: Silicoflagellate or Radiolaria? A new protist, *Bosporella tricœnoides*.—**Jean Saidman**: The comparative biological properties of high frequency and very high frequency currents. Four out of the five properties discovered by d'Arsonval for high frequency currents are shown to persist with very high frequency currents. Details of four cases treated are given.—**Mme. Z. Gruzewska** and **G. Roussel**: The α-lipase of horse serum. Its activity in multiple bleedings.—**Cl. Fromageot** and **A. Porcherel**: The action of pancreatin upon different types of wool. Different kinds of wool show differences in the reaction with pancreatin, the coarser wools proving the more resistant. The loss of weight of the wool may reach 82 per cent.—**A. Ch. Hollande** and **Mme. G. Hollande**: The cytological structure of the human type of tubercle bacillus. The evolutive cycle of *Mycobacterium tuberculosis*.

Prague.

Czech (Bohemian) Academy of Arts and Sciences (Second class, Natural Sciences and Medicine), April 17.—**K. Domin**: Races and forms of *Carex sempervirens*.—**F. Némejc**: A study of the systematic position of cones of the type *Sporangiostrobus* Bode.—**F. Novotny** and **F. Toul**: An experimental study on the estimation of traces of elementary oxygen. The Binder-Weinland method is unsuitable for detecting traces of oxygen, as the red coloration, which should indicate oxygen, is very sensitive to impurities.—**F. Bílek**: Nomographic anamorphosis in a hyperbola.

June 5.—**V. Hlavaty**: An introduction to the theory of Lie groups.—**F. Herles**: The influence of digitalis drugs as shown on electrocardiograms.—**J. Vítek**: The relation of the alkaline reserve of the cerebro-spinal liquid to the alkaline blood reserve and its bearing on the diseases of the nervous system.—**J. Babička**: Polarographic analysis with the dropping mercury cathode of extracts from plant tissues. The discovery of Prof. B. Němec that the nuclei of meristematic plant cells dissolve in hot water, whereas the nuclei of non-meristematic cells are coagulated, has been confirmed by polarographic micro-analysis. The proteins which by the action of hot water split off from chromosomes were found most abundantly in the root tips of *Vicia faba* and *Alium cepa*, whilst the other parts of the root showed a gradual diminution.—**P. Sillinger**: The species *Festucetum carpaticæ* in the Low Tatra mountains compared with an analogous association in other parts of the western Carpathians.—**B. Brauner** and **E. Švagr**: A physico-chemical study of the sulphates of the rare earths. The degree of hydrolysis has been determined in sulphates of Sc, Y, La, Ce, Pr, Nd, Sm, Gd, Tb, Er, Yb, Th by conductivity measurements of the normal and acid sulphates, by the inversion of saccharose and catalysis of methyl acetate.—**V. Hovorka**: A study of the oxidation of hydrazine and semicarbazide by potassium iodate. Free iodine, liberated in this oxidation, is bound by the addition of mercuric chlorate. The reaction is promoted by acidifying with hydrochloric acid, which dissolves precipitates formed in the reaction mixture. Excess of acid is, however, undesirable. At the end of the oxidation, potassium iodide is added and the excess of iodate determined by the iodine thus liberated.—**K. Michal**: (1) The relation between the population density and the optimum for life, and of this to the sex ratio, in some invertebrates. The animals congregate to maintain a higher temperature and humidity. The optimal conditions yield more females, whilst unfavourable conditions lead to excess of males. The deciding factor is nourishment.—(2) Oscillation in oxygen consumption during the day and during the whole life of invertebrates (meal-worm, house-fly). Maximum of oxygen consumption is reached in early morning hours, when feeding is most intense; minimum at noon. Greatest consumption of oxygen occurs when the organism is half grown, and does not correspond to the rate of growth of the body.

Rome.

Royal National Academy of the Lincei, May 3.—**G. Armellini**: The horizontal diameter of the sun in 1929 and 1930. At the Campidoglio Observatory measurements are made at noon on every clear day of the sun's horizontal diameter by four independent observers. In order that the results obtained over a series of years may be strictly comparable, the method of measurement has been kept unchanged since it was introduced by Respighi in 1876. The mean values (in seconds) thus obtained for the sun's radius during the past seven years are: 1924, 961·03; 1925, 960·63; 1926, 961·02; 1927, 961·54; 1928, 961·58; 1929, 961·63; 1930, 961·68. The causes of these more or less periodic fluctuations in the solar radius are being sought in the fact that the energy produced by the sun is not always exactly equal to the energy irradiated.—**G. Abetti**: Height of the chromosphere in 1930. Observations at Arcetri show a diminution in the mean height of the solar chromosphere from 10·38″ in 1929 to 10·28″ in 1930. The observations made at Madrid and Catania indicate decreases of 0·32″ and 0·3″ respectively. The total area of the prominences, which fell by 156 units in 1928–29, has again fallen by 291 units for 1929–30. According to the international observations collected and reduced at Zurich, the relative numbers of spots underwent reduction from 65·0 in 1929 to 35·7 in 1930, and it appears that the minimum solar activity of the present cycle starting in 1923 is not far distant.—**Q. Majorana**: New photoelectric effect in alkali metal cells.—**P. Vinassa**: Valency and symmetry. The forces acting in chemical reactions modify substances, often considerably, but either do not alter the symmetry of the components or change it into other symmetrical groupings. In the depths of the earth, rocks are fused to a magma which is greatly dissociated and ionised, but the symmetry remains unaltered.—**M. Betti and P. Pratesi**: Optical resolution of racemic aldehydes (2). By means of its reaction with β-naphthylphenylaminomethane, racemic *p*-methylhydratropic aldehyde may be resolved into its optically active components.—**F. Zambonini and S. Restaino**: Praseodymium and thallous sulphates. These sulphates form the following crystalline double sulphates: $Pr_2(SO_4)_3, 5Tl_2SO_4$; $Pr_2(SO_4)_3, 4{\cdot}5\ Tl_2SO_4$: $Pr_2(SO_4)_3, 3Tl_2SO_4, H_2O$, and $Pr_2(SO_4)_3, Tl_2SO_4, 4H_2O$.—**Giuseppe Corbellini**: The associability of *m* congruences of curves in space of *n* dimensions.—**G. Mammana**: The product of series capable of summation by Cesaro's method.—**A. de Mira Fernandes**: Centres of gravity of plane sections of a homogeneous body.—**Pia Nalli**: Rigid transports of vectors in Riemannian spaces.—**B. Segre**: Poincaré's problem of pseudo-conformal representation.—**G. Colonnetti**: Theory of arches with one or two hinges.—**G. Lampariello**: The impossibility of wave propagation in viscous fluids.—**R. Zoja**: The distribution of the tensions in a solid with rectilinear axis and with rectangular section of varying height (2).—**Paolo Straneo**: The unitary theory of gravitation and electricity (2). Presentation and preliminary discussion of the equations of the field. By development of the unitary theory previously considered, equations of the field are now deduced which are the simplest to express, at the limit, the gravitational equations of Einstein on one hand and Maxwell's electromagnetic equations on the other.—**A. Corbellini**: Stereoisomerism of derivatives of 1 : 1′-dinaphthyl. 1 : 1′-Dinaphthyl-8 : 8′-dicarboxylic acid, obtainable in good yield by reducing the diazo-compound of 8-amino-1-naphthoic acid, may be separated into its two optical antipodes by fractional crystallisation or precipitation of its brucine, cinchonine or strychnine salts. Unlike those of other analogous acids, the optical isomerides here described readily undergo racemisation in alkaline solution, even at the ordinary temperature.—**F. Rodolico**: Diopside and tremolite from Monte Spinosa in the Campigliese. The composition of the sample of tremolite analysed is in agreement in some respects with the older formula, $CaMg_3(SiO_3)_4$; if, however, the substitutions assumed by Warren (1929) are accepted, the analytical results exhibit moderately good agreement with the formula $H_2Ca_2Mg_5(SiO_3)_8$. When allowance is made for the traces of limonite present and for a certain amount of alteration which the mineral has evidently undergone, the composition of the diopside examined is in accord with the accepted formula.

Washington, D.C.

National Academy of Sciences (*Proc.*, Vol. 17, No. 8, Aug. 15).—**A. L. Shalowitz**: The physical basis of modern hydrographic surveying. Acoustic depth sounding, in addition to increasing enormously the rate at which surveys can be carried out, has led to the development of a rapid method of position-finding at sea. A small charge of T.N.T. is exploded near the ship, the sound waves are picked up by hydrophones near the shore, and automatically radio signals are sent out from a shore station. The time interval between the explosion and receipt of the radio signal gives the distance from ship to hydrophone, provided the horizontal velocity of sound in water is known. Extensive data on the latter show close agreement between measured and theoretical velocity based on bottom temperature of the sea, suggesting that the sound wave travels mainly along the bottom layers of water.—**Andrew C. Berry**: A metric for the space of measurable functions.—**Lincoln La Paz**: The Euler equations of problems of the calculus of variations with prescribed transversality conditions.—**G. A. Miller**: Theorems relating to the history of mathematics.—**Y. H. Woo**: On the intensity of total scattering of X-rays by gases (1 and 2). A general theory for a polyatomic gas is developed, assuming that only the coherent scattered radiation from the different atoms will interfere while the incoherent radiation will be simply added up. The theory gives results in fair accord with Barrett's work on hydrogen, oxygen, and nitrogen.—**E. O. Wollan**: Note on scattering by diatomic gases. Woo's results (above) accord with the author's recent experimental work, suggesting that Woo's equation is valid wherever one can assume spherical symmetry for the atoms of the gas molecule.—**Wilder D. Bancroft and John W. Ackerman**: The solid solution theory of dyeing.—**Wilder D. Bancroft and John E. Rutzler, Jr.**: Reversible coagulation in living tissue. The sensitivity of *Mimosa pudica* can be decreased by sodium thiocyanate and salicylate (peptising agents) and also by sodium citrate and amytal (coagulating agents). Experimental results suggest that anæsthetisation of plants as of animals is due to reversible coagulation of proteins which, being partly coagulated in the normal plant of *M. pudica*, account for its sensitivity.—**Barbara McClintock**: The order of the genes *C*, *Sh*, and *Wx* in *Zea mays* with reference to a cytological known point in the chromosome.—**Harriet B. Creighton and Barbara McClintock**: A correlation of cytological and genetical crossing-over in *Zea mays*. Evidence has been obtained that pairing chromosomes, heteromorphic in two regions, exchange parts when they exchange genes assigned to these regions.—Clyde E. Keeler: A reverse mutation from 'dilute' to 'intense' pigmentation in the house mouse.—Howard B. Frost: Trisomic inheritance of doubleness, complicated by lethals, in *Matthiola incana.*

Diary of Societies.

FRIDAY, December 11.

Andersonian Chemical Society (at Royal Technical College, Glasgow), at 3.15.

Biochemical Society (at London School of Hygiene and Tropical Medicine), at 3.30.

Royal Astronomical Society, at 5.—Prof. Freundlich: On the Gravitational Deflection of Light (Total Solar Eclipse, 1929, May 9).

Royal Geographical Society, at 5.—The British Expedition to Greenland (Films).

Royal Society of Medicine (Ophthalmology Section) (at Royal Eye Hospital, St. George's Circus), at 5.

Royal Society of Medicine (Clinical Section), at 5.30.

Malacological Society of London (at Linnean Society), at 6.

Institution of Chemical Engineers (at Chemical Society), at 6.

Institution of Mechanical Engineers, at 6.

North-East Coast Institution of Engineers and Shipbuilders (at Mining Institute, Newcastle-upon-Tyne), at 6.

Institution of Structural Engineers (Informal Meeting) (at Chamber of Commerce, Birmingham), at 6.30.

Society of Dyers and Colourists (jointly with Manchester Literary and Philosophical Society—Chemistry Section) (at 36 George Street, Manchester), at 7.

Institution of Electrical Engineers (London Students' Section), at 7.

Geologists' Association (North-East Lancashire Group) (at Blackburn Technical College), at 7.

Oil and Colour Chemists' Association (Manchester Section) (at College of Technology, Manchester), at 7.

West of Scotland Iron and Steel Institute (at Royal Technical College, Glasgow), at 7.15.

Society of Chemical Industry (South Wales Section) (jointly with Institute of Chemistry) (at Thomas' Café, Swansea), at 7.30.

Junior Institution of Engineers, at 7.30.

Textile Institute (Lancashire Section) (at Manchester), at 7.30.

Keighley Association of Engineers (at Queen's Hotel, Keighley), at 7.30.

Royal Institution of Great Britain, at 9.—Prof. H. J. Fleure: City Morphology in Europe.

SATURDAY, December 12.

Geologists' Association (Demonstration at Natural History Museum), at 2.30.

North of England Institute of Mining and Mechanical Engineers (at Newcastle-upon-Tyne), at 2.30.

Royal Institution of Great Britain, at 3.—Roger Fry: Great French Painters (2).

Hull Association of Engineers (at Municipal Technical College, Hull), at 7.15.

MONDAY, December 14.

Royal Society of Medicine (United Services Section), at 5.

Institution of Mechanical Engineers (Graduates' Section, London), at 6.15.

Institution of Electrical Engineers (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.

Society of Chemical Industry (Yorkshire Section) (jointly with Refractories Association of Great Britain) (at Royal Victoria Hotel, Sheffield), at 7.

Institute of Metals (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.

Royal Institute of British Architects, at 8.

Royal Geographical Society, at 8.30.

Institution of Electrical Engineers (Western Centre) (at Bristol).

TUESDAY, December 15.

Royal Institution of Great Britain, at 5.15.—Dr. F. J. W. Whipple: Air Waves and how they are used to explore the Upper Atmosphere (2).

Royal Society of Medicine, at 5.30.—General Meeting.

Institution of Civil Engineers, at 6.

Institute of Industrial Administration (Annual General Meeting) (at Institute of Hygiene), at 6.30.

London Natural History Society (Entomology Section) (at London School of Hygiene and Tropical Medicine), at 6.30.

Society of Chemical Industry (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6.45.

Institution of Electrical Engineers (Scottish Centre) (at North British Station Hotel, Edinburgh), at 7.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.

Quekett Microscopical Club (at 11 Chandos Street, W.1), at 7.

Society of Chemical Industry (Edinburgh and East of Scotland Section) (jointly with Institute of Chemistry—Edinburgh and East of Scotland Section) (at 36 York Place, Edinburgh), at 7.30.

Royal Anthropological Institute, at 8.30.

WEDNESDAY, December 16.

Society of Glass Technology (at Leeds), at 2.

Glasgow University Alchemists' Club (at Glasgow University), at 3.30.

Royal Society of Medicine (Comparative Medicine), at 5.

Royal Meteorological Society, at 5.

Geological Society of London, at 5.30.

Newcomen Society for the Study of the History of Engineering and Technology (at 17 Fleet Street), at 5.30.

Royal Microscopical Society (at B.M.A. House, Tavistock Square), at 5.30.

Institution of Automobile Engineers (Leeds Centre) (at Metropole Hotel, Leeds), at 7.15.

Folk-Lore Society (at University College), at 8.

Royal Philosophical Society of Glasgow (at 207 Bath Street, Glasgow), at 8.

Royal Geographical Society, at 8.30.—The British Expedition to Greenland (Films).

Institute of Brewing (North of England Section) (at Midland Hotel, Manchester).

THURSDAY, December 17.

Institution of Mining and Metallurgy (at Geological Society), at 5.30.

Institution of Electrical Engineers, at 6.

North-East Coast Institution of Engineers and Shipbuilders (at Mining Institute, Newcastle-upon-Tyne), at 6.

Royal Aeronautical Society (at Royal Society of Arts), at 6.30.

Royal Photographic Society of Great Britain, at 7.

Institution of Electrical Engineers (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.

Chemical Society, at 8.—Discussion on The Critical Increment of Homogeneous Reactions.

Institute of Brewing (Scottish Section) (at Caledonian Hotel, Edinburgh).

FRIDAY, December 18.

Society for Experimental Biology (in Department of Zoology, University College), at 10.30 A.M., at 2.15, at 4, and at 5.30.

Institution of Electrical Engineers (London Students' Section), at 6.15.

Royal Photographic Society of Great Britain, at 7.

Society of Dyers and Colourists (Glasgow Section) (at George Hotel, Glasgow), at 7.15.

Society of Chemical Industry (Glasgow Section) (at Royal Technical College, Glasgow), at 7.30.

Society of Chemical Industry (South Wales Section) (at Technical College, Cardiff), at 7.30.—Christmas Lecture.

Leicester Literary and Philosophical Society (Chemistry Section) (jointly with Leicester Association of Engineers) (at College of Technology, Leicester), at 7.30.

South London Botanical Institute (at 323 Norwood Road, S.E.24), at 8.

Institute of Chemistry, at 8.—Sir Frank E. Smith: The Chemist and the Community (S. M. Gluckstein Memorial Lecture).

Royal Institution of Great Britain, at 9.—Rev. Dr. C. Alington: The Education of the Average Man.

SATURDAY, December 19.

Society for Experimental Biology (in Department of Physiology, University College), at 10.30 a.m., and at 2.15.

Royal Institution of Great Britain, at 3.—Roger Fry: Great French Painters (3).

North-East Coast Institution of Engineers and Shipbuilders (Tees-Side Branch—Graduate Section) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.

Public Lectures.

SATURDAY, December 12.

Horniman Museum (Forest Hill), at 3.30.—Dr. W. G. Ivens: Negroid Peoples of the Pacific Islands.

TUESDAY, December 15.

Imperial Institute, at 2.15.—Capt. A. E. Watts: Hong Kong.

WEDNESDAY, December 16.

Imperial Institute, at 2.15.—Capt. H. Luxmoore: New Zealand.

Royal Institute of Public Health, at 4.—Sir Pendrill Varrier-Jones: The Welfare of the Tuberculous Citizen.

THURSDAY, December 17.

Imperial Institute, at 2.15.—Major G. D. Heslop: Tanganyika.

Science Museum (South Kensington) (in connexion with Exhibition of Modern Glasses), at 4.45.—J. Hogan: Stained and Painted Glass.

Official Publications Received.

University Training in Relation to Industry.

IN an address delivered at Oxford during the annual meeting of the Association of Special Libraries and Information Bureaux, Prof. A. M. Carr-Saunders suggested that in the tendency for the modern university to give professional training we are returning to the old tradition, when the prime function of a university was to equip its members for life, even though life was to them represented at first by no more than the Law or the Church. In this view he is supported by Prof. S. Alexander, who recently suggested to a Manchester audience that the inclusion of technology is the distinctive feature of university work and the best key to the understanding of the real business of a university (*Political Quarterly*, July–September).

At first sight this attitude may appear sharply opposed to the view of J. S. Mill that " Universities are not intended to teach the knowledge required to fit men for some special mode of gaining their livelihood. Their object is not to make skilful lawyers or physicians or engineers, but capable and cultivated human beings." The contrast, however, is more apparent than real, for Prof. Alexander's assertion that " What the University seeks to provide is the command of a subject, afterwards to be applied, which will make the application worthy of a free man " is scarcely to be distinguished from Mill's conclusion : " What professional men should carry away with them from an University is not professional knowledge, but that which should direct the use of their professional knowledge and bring the light of general culture to illuminate the technicalities of a special pursuit ". Essentially, however, Prof. Alexander, as much as J. S. Mill, is concerned that the graduate should acquire that sense of values which is essential to the intelligent use of knowledge. Sir J. J. Thomson, in his presidential address to Section A (Mathematical and Physical Sciences) of the British Association on Sept. 24, directed attention to the danger of over-specialisation in research courses, even in laboratories where the importance of mental training is fully realised, and asserted that the student often spends too much time in performing his experiments and too little time in thinking about them.

Sir J. J. Thomson's further remark, that methods of mass production cannot be applied to education without disaster, is of the greater interest in view of the attempts being made in Soviet Russia to provide the technicians required for the execution of the Five-Year Plan. The success or failure of this attempt at mass technical education is of intense interest to the rest of the world. The difficult conditions which prevail in industry at the present time make it indisputable that the nation whose industry commands the best brains, the most efficiently trained recruits, and the highest degree of technical skill, will have an advantage of which no artificial economic barriers can deprive it. Perhaps nowhere outside Great Britain is it more certain that the efficient training of personnel for industry is an essential factor in the permanent recovery of industrial prosperity.

Through our ubiquitous examination system, the rapid growth of knowledge in certain branches of science, notably in chemistry and in physics, has reacted on the successful candidate in a way that frequently detracts from his usefulness in industry. The danger is seen clearly enough by some, at any rate, of our teachers of science, but most of them are powerless in the grip of the system, and industry finds that its recruits are commonly well acquainted with a mass of scientific facts and lacking in the knowledge of scientific methods and principles. It must be recognised that the early specialisation in the schools, which our competitive examination system encourages, and the defective and limited teaching of general science in elementary and secondary schools, are real difficulties to the university in teaching independence of mind.

The task of utilising the sciences as a medium for imparting a training in the methods of science and of the philosophy of science is indeed herculean, and is not assisted by the suggestion that teaching is but an interlude in the proper work of a professor. The relation of research to teaching and to the examinations, which, in some form or other, can scarcely be avoided, is a crucial problem, and part at least of the present unsatisfactory situation is due to the absence of great teachers like Hofmann. Schools of science are founded by more than research, and the technique, which Major F. A. Freeth has rightly pointed out as one of their characteristics, is acquired as a result of teaching the methods and principles of science and not the imparting of facts or the prosecution of a research so as to obtain rapid results.

Although the right relation between research and teaching is the key to the situation, in Great Britain difficulties arise from the fact that, while our universities are not yet sufficiently advanced to insist on the advancement of knowledge as a necessary part of their existence, there are many who regard the prime work of a professor as research, and his teaching functions as purely subordinate and secondary. It is true that no great school of organic chemistry, for example, can be developed at a university apart from a flourishing research school. What may easily escape notice is that able teaching in the methods and technique of science inevitably results in the production of brilliant research workers whose services are widely sought and valued; whereas a brilliant investigator who cannot teach frequently gathers round him students who are schooled only in a narrow technique, the independent application of which they are unable to attempt.

The closer relations which are developing between industry and the universities may ultimately lead to a solution. In the first place, industry already recognises the importance of fundamental research work and also that this is most fittingly carried out at the universities, although not now confined to them. Once this is definitely established as a principle, the universities will have won the required public recognition that advancement of knowledge is part of their work, and can consider the relation between teaching and research without fear of prejudicing the position of the latter.

There is, however, further point in the clarification of industry's own ideas about the standard of recruit it desires, which is equally important. It is more and more widely asserted that, given an adequate training in scientific methods and principles, the particular facts which are the medium of that training matter little. Given recruits who have learnt the use of knowledge, industry will rapidly teach them the facts and problems upon which their ability is to be exercised, and more rapidly than is possible outside. Important industrial firms frequently devote much care to the training of their recruits and to discovering the particular sphere for which they are most suited, and an exchange of personnel designed to counteract the mental staleness or narrowness of outlook which doubtless account for Mr. Ford's distrust of the expert is not uncommon. Sir J. J. Thomson referred to the general experience that new ideas about a subject come when one is not thinking about it, or at least when the thread of one's thought is broken, and Prof. Graham Wallas, in " The Art of Thought ", makes the point that periods of incubation free from conscious thought on the particular problem are of vital importance to thinking. Undoubtedly, industry, no less than the university, is fully alive to the danger of mental sterility in the specialisation engendered in scientific research and to the importance of stimulating creative thought and originality.

This tendency is definitely opposed to that prevailing in Russia under the Five-Year Plan, where the old ‘ polytechnics ’ are steadily being converted into highly specialised ‘ monotechnics ’. The latter policy may be unavoidable under the present exigencies ; but, although the authorities may be alive to the importance of a proper adjustment between quality and quantity in this mass production of technicians, it seems inevitable that something of quality must be sacrificed to quantity, and there are other dangers. Science, like industry, has now reached a stage when advances come not merely from the work of specialists but also from the co-operative work of different classes of scientific workers upon specific problems, and especially from the contribution of minds which can both specialise and generalise. In this co-operative work a wider technique and wider outlook are demanded of the specialist, and this cannot be acquired in the ‘ monotechnic ’.

It is only one phase of this tendency that scientific research, whether prosecuted at the universities or in industry, is more and more concerned with the consequences of applying the new knowledge. More and more, a sense of values and of perspective is demanded of scientific as well as of industrial research, and the call for more attention to be paid to the social sciences is only one example. It should be noted that, as Flexner points out, in his recent work on “ Universities : American, English, German ” (see NATURE, Nov. 14, p. 811), this does not imply that the universities should be concerned directly with the conduct of business, politics, and industry ; but that they should select, as the material for their studies, problems of real value and bring to bear upon them a detached mind. In urging this, Flexner stresses that the business of a university is the advancement of knowledge, the study of problems from whatever source they come, and the training of men ; and he deprecates strongly the multiplication of subjects or even the prosecution of technical education at a university. The absence of values or proportion in so much of the so-called specialisation in American universities shows what a danger may lurk here. Perhaps, as already indicated, the best prospect for the application of scientific thought and method to national and world problems, enabling society to regain control over events, lies in this reflex action of industry on the universities. If society and industry look increasingly to the universities for the study of the fundamental problems of both the physical and social sciences and ensure adequate provision for the prosecution of such research, it should be easier for the universities to free themselves from the thraldom of an obsolete examination system and devote themselves to the production of graduates characterised not by their acquaintance with a multitude of unrelated and undigested facts, but by a sense of values and a judgment requiring only the ripening of experience to enable them to apply the methods and principles of science to the solution of any problem with which they may be confronted. The prime function of a university is to train intelligence, and industry cannot be satisfied with any education, university or not, which does not at least enable its possessors to attack new tasks or problems successfully.

Early Man in Kenya.

The Stone Age Cultures of Kenya Colony. By L. S. B. Leakey. With Appendices by J. D. Solomon, C. E. P. Brooks, A. T. Hopwood, H. C. Beck, and M. Connolly. Pp. xiii + 288. (Cambridge : At the University Press, 1931.) 25*s.* net.

LEAKEY here begins an account of a very marked advance of knowledge concerning early man. The luck of a good hunter and careful preparatory study along several lines have led to a great achievement. The text is commendably short, and Mrs. Burkitt has enriched it with large numbers of fine drawings. Solomon's studies of the deposits concerned add greatly to the value and interest of the book.

For beds near the Kariandusi river above Lake Elmenteita, and containing tools, Leakey and Solomon have adopted the name ‘ Kamasian ’, given by Prof. J. W. Gregory to beds he included in a Miocene series. There is obviously matter here for further investigation on both sides. All that concerns the main argument is that certain beds contain, as original constituents, Chellian and Acheulian *coups de poing,* often of fine type, many of which are flakes rather than cores. There are also chisel-like cleavers, such as have now been described for the Stellenbosch culture in South Africa and the Acheulian in Europe and North Africa.

The beds concerned include large amounts of diatomite, and bear witness to a period when large areas in the Rift Valley were under water. At the end of the period there were earth movements and volcanic eruptions, and there are indications that these occurred in a dry period.

Leakey describes next a Nanyukian culture which, for him, shows evolution from the Kenya Acheulian to the Kenya Mousterian, and may belong to the period of earth movements. This is a very tentative suggestion.

Then followed Leakey's Gamblian period, during which a lake in the Nakuru-Elmenteita region rose to 700 ft. above the present lakes, sank to below 300 ft. above them, so that parts of the lake floor became land surfaces, still recognisable by rootlet channels in the layers concerned, and then rose once more to 510 ft. (490-530 ft., for there was slight tilting later on). Above the Gamblian deposits are layers showing severe desert conditions.

During this long, but not uniform, wet period, cultures closely akin to European Mousterian and Aurignacian, but using mainly obsidian, existed side by side in Kenya, the former in the open, and over a very wide area from Kavirondo to Mombasa, as researches by Archdeacon Owen and by Mr Rickman are showing. The Kenya Aurignacian, on the other hand, belongs especially to caves. Though the Kenya Mousterian is, in Leakey's opinion, mainly a local evolution from the Nanyukian, it shows from the beginning the typical Mousterian points with faceted striking platform and secondary working. This culture develops into something akin to the South African Still-Bay phase with implements delicately worked on both faces. Burkitt thinks the Kenya Mousterians learned a lot from their Kenya Aurignacian contemporaries. Leakey apparently prefers the name Aurignacian to the name Capsian.

The Kenya Aurignacian culture lasted all through the wet period under discussion, but the evidence is chiefly from the time of the later maximum (the 510 ft. lake). Blunt-backed blades with Chatelperron points, and several types of burins, scrapers, and so on, occur. Leakey discusses specially long, thin flakes, triangular in section, often with one used edge and the opposite flake-surface showing a bulb of percussion. He thinks they are chipped-off worn edges of blocks that had been used for fine pressure-flaking. Some of these flakes were also used after being chipped away from the block; similar flakes had puzzled workers in other regions. Another type of implement has been named by Leakey a sinew-frayer; it has a rough and irregular edge used, he thinks, as are any jagged edges nowadays, by the natives. M. Breuil notes analogous tools in Europe. Leakey found some lunates in such a position as to leave no doubt that they had been mounted as barbs of a wooden arrow-head with their cutting edges forwards. Some burins were most useful tools for making grooves in wooden arrow-heads for insertion of lunates. At least two pieces of 'pottery' occurred definitely *in situ*; one was inclined to disintegrate when washed; the other was harder and patterned as if made by smearing clay inside a grass basket. Here, therefore, dies the venerable notion that agriculture antedates the invention of pottery, unless, indeed, this culture in Kenya is very late or the pottery is accidental. Other finds include ostrich egg-shell beads, some apparently deliberately stained. Human remains are more like those of ancient Europeans than of any peoples of torrid Africa, and they are to be described in a later volume.

After the intensely desertic period the lake redeveloped with diatomite deposits. This wet period, called by Leakey Makalian, is represented only by thin deposits containing a late and aberrant development of the Kenya Aurignacian culture with large quantities of pottery. To this culture Leakey gives the name Elmenteitan, and one may commend the care with which he has created separate names for cultures and for periods determined by climate. One site of this phase of culture yielded a number of non-African skeletons, some with very narrow noses.

Multitudes of microliths in Kenya, as in North Africa and Europe, end the palæolithic phase of culture. Leakey adopts for this industry the name of Kenya Wilton, because of resemblances to the Wilton industry in South Africa; there is a good deal of associated pottery.

The neolithic cultures of Kenya are briefly discussed, pending further work. They are named Gumban *A* (with pottery, lunates, scrapers, stone-bowls, etc.) and Gumban *B* (with stone-bowls, pottery, tools of obsidian, and bone and beads). These finds accompanied burials, and one cannot say which is earlier. The Njoroan culture yields burials which, unlike all earlier ones, are extended full length; one polished axe has been found in a burial and others occur casually. Obsidian flakes continued in use.

Absolute dates for this important series of cultures are a problem, and, with characteristic courage, Leakey, supported in large measure by Wayland, C. E. P. Brooks, and Miss Caton-Thompson, makes his chief pluvial periods contemporary with Pleistocene ice maxima in Europe. The Kamasian, containing Chellian and Acheulian tools, he associates with the older maxima, called, in the Alpine region, the Gunz and the Mindel. His succeeding dry interval would then be correlated with the long Mindel-Riss interglacial, a period, according to central European glaciologists, of climates warmer than the present one and fairly moist, as evidenced by the finds in the Hötting breccia. The second long wet period, the Gamblian, would, on the same basis, be correlated with the Riss and Würm maxima of the Alpine glaciation. This scheme is broadly useful as a working hypothesis.

The slighter Makalian wet phase is correlated by Brooks, and by Leakey and Solomon, with what used to be called the Bühl re-advance during the post-Würmian ice retreat. Here we have some doubts. There seems little indication that between the Würm and the Bühl stadia in the Alps, or between stadia that have been supposed to be more or less their contemporaries in the Baltic, there was any really warm period; and, if the correlation of European and African stadia is maintained, the intense desertic conditions between Gamblian and Makalian in Kenya would suggest a very marked climatic oscillation in Europe between Würm and Bühl. It might, therefore, be well to keep in mind as an alternative hypothesis, if the correlation of climates has anything in it, that the Kenya Gamblian covers what in the Alps includes Riss, Würm, and Bühl. This makes it conceivable that the upper Aurignacian of Kenya may not be of quite such immense antiquity as it would otherwise be necessary to imagine. The Elmenteitan culture, of the Makalian wet phase, might on this view be contemporary with one of the minor and later regrowths of glaciers in Europe, for example, that described for the Alps as the Gschnitz. In any event, however, this study of climatic correlations is only in its infancy.

If the lower Aurignacian reached Europe across the Mediterranean from North Africa, and the middle Aurignacian reached our continent from the Palestinian region, we can picture a little of early culture spreads from both north and south sides of what is now the great zone of hot deserts in northern Africa and south-west Asia, but was less desertic then. The resemblances in implements, and to some extent in human types, suggest that the two spreads (north and south) may not have been separated by a long period of time.

The poverty of evidence of anything analogous to the Kenya finds farther west in Africa seems not entirely due to lack of investigation, and one recalls Falconer's interesting conclusion in Nigeria, that, in Pleistocene times, before the Sahara had become fully desertic, a desert belt lay farther south, as one would expect if there is anything in the hypothesis of climate correlations based on shifting of the main climatic zones. A desert belt would limit the spread of early man, but the Nile might well give him a way southwards into the east of Africa. Orographical changes in the later Pleistocene in the Red Sea region may have helped movements between Arabia and Africa and southward in East Africa.

Those interested in prehistoric man will have noted the important parallels between some of the early Kenya cultures and those of South Africa. This is a subject receiving new illumination from van Riet Lowe, Goodwin, and Breuil, and from Armstrong's results from Bambata, Rhodesia, and more may be expected from the joint work of Reck and Leakey in Tanganyika. South African cultures seem to be the drifted descendants, having also sometimes intermingled *en route*, of some of those of Kenya. The later volume on physical types of men will link itself with Broom's interesting studies in South Africa.

Leakey's work bristles with points of wide interest and invites discussion of big principles; there may be modifications of hypotheses in the future, but the hypotheses are at any rate very promising and serviceable, and the work done is first-rate.

The Development of Formal Logic.

A Treatise of Formal Logic: its Evolution and Main Branches, with its Relations to Mathematics and Philosophy. By Prof. Jørgen Jørgensen. Vol. 1. Pp. xv+266. Vol. 2. Pp. iv+273. Vol. 3. Pp. iv+321. (Copenhagen: Levin and Munksgaard; London: Oxford University Press, 1931.) 60*s*. net.

OF all the branches of philosophy, logic alone has had the distinction of being claimed by the exact sciences as one of them. The event is of recent occurrence; in fact, it has happened only since logic has taken to mathematical symbolism. So long as logic reigned over philosophical logomachies, it was scarcely differentiated from normative philosophy; and it has cost a great deal of hard thinking to bring it by degrees within the favours of the exact sciences. Why logic slumbered in the linguistic bliss devised by Aristotle's genius, and how it was awakened to a nobler destiny, is a story of great importance and interest for the student of mental sciences. It is this story which Prof. Jørgensen tells us in his present work, in which real scholarship is happily federated with the easier ways of education.

Prof. Jørgensen points out very adequately that formal logic now consists of three main branches, which mark the three principal stages of its historical development: classical logic, the algebra of logic, and logistics. In the first volume, he gives a critical survey of the history of these three branches up to the present day: while he devotes the second volume to a systematic exposition of the principal parts of these branches, with critical observations on their relative advantages and defects. The third volume deals with the relations between formal logic and mathematics; it discusses the various methods of establishing the foundations of mathematics, and examines in particular the theory of logical types. Finally, the author investigates the relations between logic and philosophy, and certain aspects of psychology and linguistics, and indicates the grounds for the validity of formal logic.

A very useful background to the problems discussed is given by the historical development of logic, from the Greek works on mathematics which contain "the earliest known attempts at establishing rational, logically constructed, and abstract thought contexts", to the "Principia Mathematica" of Russell and Whitehead. What characterises this survey is the indication of the constant connexion between logic and mathematics. This, however, does not prevent the author from stigmatising classical logic as an "artificially restricted system, the fossilised form of a very early and imperfect stage in the evolution of the science", as "a mixture of faulty attempts at a formal deductive logic and the philosophy of formal logic".

On the basis of these drastic pronouncements—which, however, seem to us rather unfair in the light of history and of the services still rendered by classical logic—the author proposes to replace classical deductive logic by the algebra of logic and logistics, while the old philosophy of formal logic should give way to a more profound investigation and analysis of the real and ideal presuppositions of the sciences in question. Thus, he thinks that

> "formal logic disappears from the ranks of the philosophical sciences, and becomes a special science, the foundations of which, however, may still be subjected to philosophical investigation. So that the 'philosophy of formal logic' remains a philosophical science occupying the place of 'logic' in the system of philosophy, and having for its principal objects the discovery, analysis and arrangement of logical forms, an adequate symbolization of the logical forms, and the investigation of the conditions governing validity of the logical forms. It will require here the support of linguistics and psychology, especially the psychology of thought" (vol. 3, p. 294).

The technical outline of the algebra of logic and of logistics or mathematical logic (vol. 2) is a most welcome contribution to these difficult subjects, as the source books and memoirs are not easily accessible to the general student who approaches them for the first time. The epitome of the theories of the earlier mathematical logicians, such as Schröder and Frege, which is given in vol. 1, introduces very aptly this part, as it illustrates the progress in the analysis of the elements of thought and in the ideography employed. The distinction between the algebra of logic and logistics is worth mentioning here. The former is considered as "an attempt to apply the algebraical method to the exposition of the doctrinal system of logic and to the solution of logical problems". Originally, the algebra of logic was considered as a kind of algebraical translation of classical logic, which assumed thus a more general character in its new dress. Its later development, however, turned it into an independent mathematical theory; so that now its relation to logic lies only in the fact that logic is one of its possible applications. As the algebra of logic, however, asserts nothing as to the existence of objects satisfying its axioms and theorems, it is entirely a hypothetical deductive system, and as such, it assumes previous knowledge of the logical constants and the validity of the logical principles of deduction.

On the other hand, the "chief aim of logistics is to reduce pure mathematics to formal logic, so that these two sciences are made to form a systematic whole". Logistics differs from all other deductive theories in utilising the principles of deduction themselves as its primitive propositions, which must be therefore materially true. If the whole of formal logic and pure mathematics could be deduced solely from these principles, all dispute as to their foundations and validity would be at an end. Prof. Jørgensen thinks, however, that logistics is not yet elaborated to completeness. It has been obliged to establish three additional principles—the axiom of reducibility, the multiplicative axiom, and the axiom of infinity—the material truth of which is not yet proved.

This serious defect, along with other difficulties, lead Prof. Jørgensen to suggest the most important problems to be solved before the foundations of formal logic and pure mathematics can be regarded as quite in order. These are as follows: (1) How many different logical forms and constants are there? (2) How far is it possible to reduce their number by means of nominal definitions? (3) How can they be most adequately symbolised? (4) What is the relation between formal and informal premises in the various deductive theories? (5) Are all compound objective forms truth-functions? (6) Can the principle of the excluded middle be applied to infinite manifolds? (7) What are the conditions required to render a system of axioms complete in the sense that all problems concerning its objects can be solved unequivocally on the basis of its axioms? (8) Are the axioms of reducibility, the multiplicative axiom, and the axiom of infinity necessary, or can they be replaced by more satisfactory axioms or perhaps dispensed with altogether? (9) Wherein lies the paradoxical deception in the logical-mathematical paradoxes?

These are very serious difficulties, though Wittgenstein, Chwistek, and Ramsey seemed to have cleared the theory of logical types of some of its blemishes, indeed, and suggest to one that the ideal of absolute deduction is only a pious hope. It will be probably experienced that attempts to dispense with any of these difficulties will only change the terms of the problem. If we make up our mind that no perfect human science is possible, then we do not see why, as Prof. Jørgensen suggests, it is futile to discuss the general problems as to the nature and relations of logic and mathematics, grammar, or psychology until the major difficulties of logistics are satisfactorily solved. Science and philosophy cannot mark time; their greatness lies in their heroic uncertainty as to the ultimate nature of things.

THOMAS GREENWOOD.

The Works of Scheele.

The Collected Papers of Carl Wilhelm Scheele. Translated from the Swedish and German originals by Dr. Leonard Dobbin. Pp. xvi + 367. (London: G. Bell and Sons, Ltd., 1931.) 10*s.* net.

THERE has not previously been available an English account of the investigations of Scheele in a single volume. The present work supplies this defect, and, since it has been translated afresh from the original sources, it also has the character of a critical edition. The edition of Hermbstädt, in German, which has usually been considered authoritative, contains errors not present in the Swedish originals, this latter being the language in which Scheele wrote his memoirs. This is an important point, since it has often been considered that Scheele wrote in German and that the Swedish versions were translated from the German. Dr. Dobbin shows quite conclusively that the opposite course was, in fact, followed. The rugged style of the originals has been preserved in the translation, and although some modifications have been made in the punctuation and division of sentences, the text reproduces faithfully the individuality of the originals. This was a wise course of procedure and one which is much to be commended. The index is full, and there is a short but adequate appendix of modern equivalents of the chemical names used by Scheele.

The amount of chemical work done by Scheele in his spare time as a small retail tradesman in drugs in an insignificant Swedish town is amazing. His guiding theories were nearly all wrong and his contributions to chemical theory are as good as nothing. But it is very instructive to see him, guided step by step along the lines of a totally incorrect working hypothesis, reaching experimental results of the highest importance, and to perceive how it would have been possible to work back from these and to reach a different theoretical interpretation. His method of work was essentially qualitative, although he was very skilled in the use of the balance, and at some points, as when he was able to show that nitrogen was somewhat less dense than air, he turned this to advantage. He very often gives us the weights of the materials he employed and of the products obtained, but the data are usually given more from the point of view of preparative detail than from that of quantitative investigation.

Among the new substances discovered by Scheele, and his original investigations, may be mentioned the independent discovery of oxygen, the discovery of chlorine and of barium compounds, of the solubility of manganous carbonate in water containing dissolved carbon dioxide, of the formation of manganates and permanganates, of the action of the different parts of the solar spectrum on silver chloride, of the discovery of hydrocyanic acid and several cyanides, of glycerol and several organic acids, of manganous dithionate (see p. 18), of a new method of preparing benzoic acid, of arsenic hydride (of the poisonous properties of which, as well as those of hydrocyanic acid, he was not aware), of many analytical methods, of hydrofluoric acid, tungsten and molybdenum compounds, and a large number of improved methods of preparation of substances already known. All this work was carried out with the very simplest apparatus, such as glass and clay retorts, bottles, dishes, and bladders available in the pharmacist's shop. If Scheele had any fundamental philosophical guiding principle, it was probably that which he expresses as follows (p. 77): "My practice with chemical statements is never to believe any of them until I have proved them by making experiments"—an attitude which was afterwards adopted by Dalton.

It is impossible to give in a few words any adequate appreciation of Scheele's scientific importance. "Really to know and appreciate Scheele," as Dr. Dobbin says, "it is necessary to read and study his papers attentively in detail." The translation includes the famous treatise "On Fire and Air", which laid the foundation of its author's reputation throughout Europe. This treatise and most of Scheele's other papers contain innumerable discoveries, announced in short and unpretentious statements, which reveal a master of experimental method.

Dr. Dobbin's translation is to be welcomed as a careful and authoritative work, and one which makes available to chemists a collection of memoirs of the greatest interest and importance. The printing and paper are excellent, and the book is one which chemists will read with interest and with a growing admiration for the great Swedish experimenter.

Coal and its Use.

(1) *Entstehung, Veredlung und Verwertung der Kohle.* Vorträge, gehalten an der Deutschen Technischen Hochschule in Prag von W. Petrascheck, H. Apfelbeck, H. Tropsch, R. Heinze, A. Czermak, E. Kothny, H. Löffler, A. Rozinek, J. C. Breinl. Herausgegeben im Auftrag des Professorenkollegiums von Prof. K. A. Redlich, Prof. J. C. Breinl und H. Tropsch. Pp. vii + 359. (Berlin: Gebrüder Borntraeger, 1930.) 30 gold marks.

(2) *Die Chemie der Kohle.* Von Dr. Walter Fuchs. Pp. viii + 510. (Berlin: Julius Springer, 1931.) 45 gold marks.

(1) THIS book is a reprint, in an enlarged and revised form, of several lectures, by different authors, having reference to the general subject of the origin, improvement, and utilisation of coal. Naturally, the whole subject could not be covered. The individual lectures vary greatly in range of subject and thoroughness of treatment, with the result that the book has a somewhat disjointed character.

Nearly half the available space is taken up by R. Heinze's dissertation on the drying and carbonisation of brown coal (157 pages and 49 illustrations). This might well have been printed separately, and gives much information not so conveniently available elsewhere. There are sections on the nature of the raw material and of the products, besides illustrations of most forms of drying and carbonising plants. The value of the book to a given reader must depend largely on this chapter.

H. Tropsch is responsible for two lectures, one on the origin and chemical structure of coal, and the other on syntheses from gases obtained from coal. The former is a useful summary of the views of the German school of coal research; the latter deals with the preparation of liquid fuels by the pyrolysis of methane and ethylene, besides the now familiar hydrogenation of carbon monoxide to give methyl alcohol, etc. The recent experiments, in which liquid paraffins were obtained by working at atmospheric pressure, are described in considerable detail.

Of the others, the most interesting lectures are perhaps those of W. Petraschek (on the geological aspect of coal formation) and H. Apfelbeck. The latter has many interesting graphs showing changes in composition during the coal-forming process, but the lecture would be improved by more references to previous work. The remaining lectures can only be mentioned—E. Kothny, on the economic and thermotechnical significance of coal; H. Löffler, on the burning of solid fuels; A. Rozinek, on the Szikla-Rozinek process of firing with producer gas from pulverised fuel; and J. C. Breinl, on theoretical principles of the mechanical regulation of firing.

(2) The chemistry of coal has not in the past attracted many first-rate chemists. Numerous investigations have nevertheless been carried out, shedding a good deal of light on this difficult problem, and indicating many promising lines of future progress. Further information is, however, badly needed, especially in connexion with the newer methods of coal treatment, such as the Bergius hydrogenation process. Any organic chemist lacking a subject for research may be recommended to read the book under review.

Fuchs's method is to start with the living plant. The first chapter gives an admirable summary of present knowledge of the chemistry of plant products, and goes on to discuss the processes of decay that take place in Nature. Then follow lengthy chapters on peat, brown coal, and bituminous coal. These chapters have the character of self-contained monographs. The information on peat and brown coal should be especially useful to English readers. The matter is very systematically arranged—definition, varieties, and mode of occurrence; petrographic, physical, and chemical properties; chemistry of the constituents; response to various chemical, physical, and biological treatments; discussion of the mode of origin.

The final chapter restores the continuity by dealing with the comparative chemistry of the various fuels.

The author has succeeded in being comprehensive without undue prolixity. Every important piece of work seems to be mentioned, and references are given to the whole of the modern literature, both in German and other languages, up to the early part of the current year. Matters of purely historic interest are purposely omitted. One feature perhaps lending itself to criticism is the almost complete absence of graphs, which in many places might advantageously have been introduced to summarise experimental data.

The book is well printed and bound. The price is unfortunately high, but the coal chemist cannot afford to dispense with it. It is to be hoped that an English translation will be published.

R. WIGGINTON.

Short Reviews.

Handbuch der vergleichenden Stratigraphie Deutschlands. Herausgegeben von der Preussischen Geologischen Landesanstalt. *Alluvium.* Schriftleitung, J. Stoller. Unter Mitwirkung von K. von Bülow und W. Dienemann. Pp. xii + 424. (Berlin: Gebrüder Borntraeger, 1931.) 30 gold marks.

IN this " Handbuch ", issued under the auspices of the Prussian Geological Survey in association with other German surveys, it is proposed to furnish a complete account of the German stratigraphical succession. The distribution, especially with regard to facies, the petrography, palæontology, tectonics, economics, and the whole genesis of each geological formation are to be described ; where possible, geological maps are to accompany each volume. The " Handbuch " is to be completed in twelve volumes, of which this on alluvium is the first. The other volumes are to deal with Diluvium, Tertiary, Cretaceous, Jurassic, Trias, Zechstein, Rothliegendes, Carboniferous, Devonian, Silurian-Cambrian, and Crystalline Schists. The publication of a work of this scope is obviously an event of first-class importance in the study of European geology.

Fourteen authors have contributed to the present volume, " Alluvium " ; their work has been collated by the late Prof. Jakob Stoller, with the help of K. v. Bülow and W. Dienemann. All deposits formed since the melting of the last ice-sheet come within the scope of this volume. The treatment is based upon the facies classification of v. Bülow—marine, freshwater, continental. The North Sea and Baltic marshes and coastal deposits form the first facies, lacustrine and fluviatile deposits the second, whilst in the third are grouped dunes, calc-sinters, peat, and landslips and related deposits. The origin, distribution, and petrography of each type are exhaustively discussed. The flora and fauna of ' Alluvium '—in the sense used in this work —are employed in the elucidation of the climate of the time. The volume ends with a summary of the products of economic value derived from the alluvium. Lengthy bibliographies are appended to each section.

A large folding table, by v. Bülow, gives the classification and correlation of the various types of deposits considered in this work, with their corresponding floral, faunistic, and archæological characteristics.

Paläoklimatologie. Von Dr. Fritz Kerner-Marilaun. Pp. viii + 512. (Berlin: Gebrüder Borntraeger, 1930.) 39 gold marks.

DR. KERNER-MARILAUN, an Austrian mining geologist, has since 1895 issued a long series of papers on former climates, and his contributions have been marked by recognition of the uncertainty of evidence on which reliance was once firmly placed, and by ingenuity in the application of many different lines of investigation. In the present work he has summarised the nature of the available evidence and discussed its value.

The book is divided into six parts, as follows: the various kinds of evidence as to former climates ; the character of established ancient climates ; their causes, including elevation above sea-level, distribution of land and water, the influence of latitude, the wandering of the poles and variations of latitude, fluctuations in solar radiation, and the influence of sunspots and volcanic dust ; methods of estimation of climatic factors (or thermogeographical analysis) ; the evidence of palæogeography and geochronology ; and finally, consideration of the various theories of former climatic changes. The work consists mainly of a statement and discussion of the principles of palæometeorology, and its chief value is as a summary of the conflicting hypotheses rather than an exposition by the author of his own conclusions.

The book uses a highly technical terminology and fortunately thirty-one of the author's own terms are explained in a glossary: eight of them deal with the evaluation of the evidence. The author quotes a large number of authorities, but without references ; sometimes a clue is provided by mention of the date, but as a rule the author's name only is given. The lack of references is a serious defect, especially having in view the scattered nature of the evidence—botanical, geographical, geological, and physical. The index is also poor and incomplete.

Integrative Psychology: a Study of Unit Response. By William M. Marston and C. Daly King and Elizabeth H. Marston. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xvi + 558. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., 1931.) 21*s.* net.

" INTEGRATIVE PSYCHOLOGY " stands midway between the classical school of introspection and psychoanalysis. It claims to organise the subject matter of psychology and to give its adherents practical knowledge about themselves, applicable to the personal problems of their everyday lives.

The fundamental principle of integrative psychology is to emphasise the 'You' instead of the 'I', and has many claims in its favour. For example, 'I' cannot observe himself without becoming a different 'I' from that which he set out to observe; and this change is likely to affect the truth and value of his observations. On the other hand, the study of an objective element such as 'You' allows for a more accurate application of scientific method to the various problems of psychology. Integrative psychology, however, does not imply contact of the organs by environment, and thus offers a more adequate analysis of personality than behaviourism, although it does not repudiate altogether the idea of being, in a sense, mechanical. Yet it regards the integrative mechanism of human beings as a spontaneously operating device whereby the human organism may be completely freed from environment or materialistic control.

On these fundamental principles the authors of the book under review build up a very comprehensive and attractive system of psychology, in which the biological background of that science helps to explain drives, sensation, emotion, consciousness, reasoning, and personality. It would be difficult to admit, however, that integrative psychology offers a complete and self-contained alternative to the older schools of psychology.

T. G.

Tales told in Togoland. By A. W. Cardinall. To which is added the Mythical and Traditional History of Dagomba, by E. F. Tamakloe. (Published for the International Institute of African Languages and Culture.) Pp. vi + 290. (London: Oxford University Press, 1931.) 16*s.* net.

In "Tales told in Togoland", Mr. Cardinall has made a valuable addition to the literature both of the folk-tale and of ethnography. His stories are drawn from the peoples of that part of the former German colony which has been attached to the Gold Coast for administrative purposes. In the belt of it with which he deals more particularly are peoples who are entirely unknown to anthropological science, some of them retaining traces of their ancient customs which are untouched by outside contact.

The tribes differ considerably one from another in culture. Among the more advanced the influence of Ashanti has been considerable. Notwithstanding these differences, the lore of the people and their fairy tales are very similar throughout the area and often identical. Mr. Cardinall has drawn his information from the people, peasants, hunters, and farmers, and not from the chiefs and priests. He offers some interesting comments on the stories, which range from "Just So" stories to native history. He suggests an origin for Brer Rabbit—not the chevrotain as usually held, but actually the hare—and puts forward an explanation of the transformation of the hero of the folk-tale into Ananci, the spider, which is more than probable. While thanking Mr. Cardinall for his diverting, but none the less highly instructive collection of tales and the accompanying commentary, we join with him in deploring the probability that these interesting tribes will have lost much of their primitive habit of mind and custom before they have been studied by a trained anthropologist.

Elementary Hyperbolics: for Technical and other Students; specially adapted to the Requirements of Beginners. By M. E. J. Gheury de Bray. In 2 vols. Vol. 1: *Hyperbolic Functions of Real and Unreal Angles.* Pp. xi + 351. Vol. 2: *The Applications of Hyperbolic Functions.* Pp. xii + 209. (London: Crosby Lockwood and Son, 1931.) 7*s.* 6*d.* each vol.

This work is by the author of "Exponentials Made Easy" and is in the same colloquial and humorous style, with chapter headings like "Where We meet again an Old Acquaintance, and with its Help, venture into a Maze and discover a Treasure Buried therein". On p. 294 we are told that "Infinity is a mysterious region: there things happen which do not happen anywhere else. There, for example, parallel straight lines meet, a thing which no properly brought-up parallel straight lines will ever do elsewhere (in Euclidean geometry). . . ." The first volume gives the ordinary mathematics of complex numbers, exponentials, hyperbolic functions, and the easier parts of analytical trigonometry, but in much more detail than usual, as the author is writing for engineers of limited mathematical powers. The proofs on pp. 64-66 are given without any mention of their weak points. The second volume, dealing with the application of hyperbolic functions, appears to be much more valuable. Most of it is concerned with electrical engineering; the rest deals with geography, navigation, strength of materials, suspension bridges, and cables.

H. T. H. P.

Der Smekal-Raman-Effekt. Von Prof. Dr. K. W. F. Kohlrausch. (Struktur der Materie in Einzeldarstellungen, herausgegeben von M. Born und J. Franck, Band 12.) Pp. viii + 392. (Berlin: Julius Springer, 1931.) 33·80 gold marks.

This book gives a summary of work on the Raman effect up to the middle of this year. It is necessarily largely a catalogue of numerical data, but does also contain both a good general elementary account of the subject and the essential parts of its rather complicated mathematical basis. The arrangement of the material—and it is remarkable how much has been accumulated in three years—is excellent and the author's comments authoritative and critical, so that there can be little doubt that the book will come to be the standard reference for early investigations in this still young subject. At the moment the most valuable parts for the research worker will probably be a table of Raman spectra for 482 substances, classified according to their chemical composition, and a list of 417 original papers. Incidentally, is it not time either that the phenomenon came to be described simply as the Raman effect, or that some generally acceptable designation were devised expressing its physical content?

K. G. E.

The Changing Outlook in Agriculture.*

By Sir JOHN RUSSELL, O.B.E., F.R.S.

AGRICULTURE as an art was already far advanced when the first meeting of the British Association was held in 1831. It was then entirely empirical. Scientific work was, however, beginning, and round about 1840 three important events occurred: Liebig published his epoch-making essay on the application of chemistry to agriculture, Lawes began the famous Rothamsted experiments which almost at once led to the founding of the artificial fertiliser industry, and the Royal Agricultural Society started its beneficent work of fostering the application of science to practice. Economic conditions favoured the growth of the home agriculture, and from about 1850 to 1890 British agriculture flourished. Then within a few years it collapsed. The chain of transport arrangements with the United States and Canada was completed and farm produce came on to our markets at prices with which British agriculturists could not possibly compete.

The overseas systems were inferior to our own in production per acre, but the shortage of population had necessitated the development of labour-saving machinery, so that the production per man was greater, and this higher efficiency of output won the day. British farmers suffered greatly; many became bankrupt.

Gradually it was realised that the way out of the difficulty was to specialise, and this specialisation favoured the application of science to agriculture. From 1889 onwards, when the Board of Agriculture was founded, agricultural colleges began to grow up. The pioneers of those days—Middleton, Wood, Gilchrist, Somerville, Percival, F. B. Smith—to name only a few, had a strenuous uphill task. But the pioneers kept on with their struggle, and, inspired by the faith that was in them, they carried agricultural education through the length and breadth of the countryside.

Then came the system of county agricultural organisers. These now play so great a part in British agriculture that one is apt to forget that they began only about 1900. The present widespread system was set up only in January 1919, when the Board of Agriculture, as it then was, circulated to the counties proposals for a comprehensive system of agricultural education, offering to pay 80 per cent of the organiser's salary and 66⅔ per cent of all other approved expenditure. With the organisers have grown up the farm institutes, and now there are springing up everywhere discussion societies where farmers meet to discuss technical and other matters of importance. At first no provision was made for research; then it was realised that agricultural education could not be carried on without research. Research on any important scale became possible only after 1909, when the Development Fund of £2,000,000 was set up at the instance of Mr. Lloyd George for a variety of purposes, including research.

The Development Commissioners at the outset adopted the wise policy of allocating the several sections of agricultural science to existing institutions, making grants on an adequate basis, and so ensuring a widespread interest and, perhaps more important, a widespread net to capture young and capable research workers. Crop production (soil, plant nutrition, and plant pathology) was placed at Rothamsted, animal nutrition at Cambridge and the Rowett Institute, plant genetics at Cambridge and Aberystwyth, animal genetics at Edinburgh, agricultural botany at Cambridge, dairy research at Reading, fruit at Long Ashton and East Malling, economics and engineering at Oxford, horticulture and low temperature research at Cambridge, veterinary research at Cambridge and Weybridge, helminthology at the London School of Tropical Medicine, glasshouse horticulture at Cheshunt.

The scheme is worked through the Ministry of Agriculture, and it is one of the best instances of successful combination of Government supervision of finance with adequate freedom of action for the research worker. The general result of all these activities has been that farmers have learned to cheapen production, to seek profitable outlets for their industry, to use machinery and any other aids to production. Results soon appeared. When Hall, in the years 1910–12, made his classical pilgrimage of British farming, he records as his general impression that "the industry is at present sound and prosperous". This was less than twenty years after the deep depression of the early 'nineties.

Then came the War. For the British, for the overseas Empire and the United States, it was a time of feverish activity to raise more food to sell to the Allies. Prices were fixed in England, so that money never abounded in the countryside as it had done in Napoleonic times. In spite of the sadness of the War years, the farmers of Great Britain put up a wonderful fight to produce food. After the War came three years of high prices; in 1920 wheat averaged 80*s.* 10*d.* per quarter, the highest since 1818. Then just as suddenly there came the slump; by 1922 wheat was down to 47*s.* 10*d.*

The high prices had done farmers very little good, and in the end they lost all that they had gained. Many landowners proceeded to sell their estates. The high price of produce induced many to bid for the land, and the sitting tenant had either to outbid or be dispossessed. Frequently he had to pay more in interest on loans and mortgages than he had paid in rent, and in addition he has also to maintain the buildings, gates, and roads which formerly the estate had done. He is therefore in a far worse position than the farmer of 1821 in the slump after the high prices of the Napoleonic wars.

Much worse has come. When the first rush of cleaning up after the War was over, it was realised that the world's power of producing food had grown far in excess of its power of consuming food. The population had increased but the power of food production had increased much more. In consequence, prices of farm produce have fallen far more than costs of labour and of other commodities. British farmers have turned, as in the 1890's, to live stock, raising lamb, young pigs, and milk so far as possible on grass with an increasing acreage of lucerne, thanks to the success of Thornton's inoculation method. Those who cannot produce grass cheaply and easily, but who have to depend on arable land, are in a sorry plight, and the difficulty is not confined to Great Britain; arable farmers in all civilised countries are deeply depressed.

---

* From the presidential address to Section M (Agriculture) of the British Association, delivered in London on Sept. 25.

This certainly is not the result that was expected; on the contrary, experts had confidently predicted a food shortage. Sir William Crookes, in his presidential address to the British Association in 1898, forecast the probable world requirement of wheat for the next three decades, and showed that the sources and methods then available would continue to suffice only until 1931, when the world would begin to feel the pinch of hunger. Crookes's figures were remarkably accurate, and there can be no doubt that, had science and practice stood still since 1898, we should now be facing the horrors of world starvation. But they have not stood still, and the present position of farm prices is a measure of their advancement.

Two new and closely linked factors have come into play since 1898 and are largely responsible for the present position: the widening of the scope of science in agriculture and the agricultural development of the British Empire and of South America. In the nineteenth century agriculture had been mainly a branch of chemistry; its professors had been chemists, its laboratories chemical. Crookes suggested more chemistry as the way out of what he called the 'colossal dilemma' of world starvation; he proposed the manufacture of more nitrogenous fertilisers from the air—a fantastic idea at the time, yet now our chief source of supply.

The new scientific developments came from the biological side, and the new practical developments from the engineering side. The first great biological triumphs were in plant breeding. Canada affords some of the best examples of the plant breeder's success in opening up new regions of the world for settlement. Up to the middle of the nineteenth century the Canadian wheats were suited only to the eastern provinces, Ontario and Quebec; they were uncertain on the prairies. About 1842, David Fife, in Ontario, received for trial from a Glasgow friend several packets of wheat, which he sowed. Among the resulting plants was one that differed entirely from the rest, and also escaped damage from rust and frost, two destroyers of wheat in those times. How the seed got there, or whence it came, can never be known. It was a Galician variety. But the accident was a fortunate one for Canada, and did much to build up her wealth. The wheat plant was so good that Fife saved the seed and multiplied it, and in course of time it was widely taken up by farmers under the name of Red Fife. It proved to be eminently suited to the prairies, and as soon as the railway was completed in 1886 it was taken there by the new settlers and became the basis of their prosperity.

Man-power was long the limiting factor in Canadian farming, and this problem of saving labour has been attacked with devastating thoroughness by engineers all the world over. The tractor and the new cultivating implements at and before seeding-time, and the combine at harvesting, have revolutionised wheat-growing by dispensing with enormous numbers of men and greatly increasing the area of land needed per man as an economic unit for wheat farming. Not long ago 160 acres was the economic unit for the family farm; now 320 acres is the lowest limit, and 640 acres is nearer the most profitable size.

Australia also has developed as the result of the activities of the plant breeder and the engineer; the problem here was the conquest of the drought. Farrer began by producing wheats more resistant to rust and drought than the older sorts, and his pupils, Sutton and others, have continued the work. Agriculturists showed the great value of superphosphate for all crops; they further improved the methods of cultivation, and now, as A. E. V. Richardson has shown, for each inch of rain falling during the season, the farmers of Victoria obtain one bushel of wheat, while forty years ago they obtained only half a bushel.

South Africa owes much of its advances to two other branches of biological science—veterinary science and parasitology. No part of the white man's habitation seems so suitable for insects, and especially parasites, as South Africa. So long as the white man occupied the country only thinly he could do it without difficulty, but trouble began as soon as he wished to increase his hold on the land and multiply his flocks and herds. The first to attack the problem seriously was Arnold Theiler. He founded the Veterinary Research Laboratories at Onderstepoort, of which not only South Africa but also the whole Empire is proud, and he trained up a body of veterinary research workers and officers who now, under the distinguished leadership of P. J. du Toit, are extending the good work.

We are still far from security; in the past twelve years foot-and-mouth disease has cost the British Government more than 5½ million pounds sterling, paid to the farmers of Great Britain as compensation for animals compulsorily slaughtered, while the farmers themselves have suffered vastly more. Veterinary research is now developing at Cambridge and elsewhere, and the relationships between nutrition and disease are studied at the Rowett Institute.

The engineer has perhaps been the greatest force in the development of New Zealand agriculture. The invention of refrigeration paved the way for the great dairy and lamb industries, which are now among the most remarkable and efficient agricultural industries in the world. The exports are rapidly rising. In 1929 that of butter was valued at £13·2 millions, of cheese £7 millions, frozen meat (mutton and lamb) £9·9 millions; in all, more than

£30 millions by refrigeration transport, as against £15 millions of wool—a truly remarkable progress.

The development of the dairy industry, however, was not simply a matter of transport: it is a triumph for the bacteriologist. In Great Britain good work has been done at the Dairy Research Institute at Reading by Stenhouse Williams, Golding, and their colleagues. Australia has recently made great progress with the dairy industry, and is now going into the question of lamb. Canada has a highly developed dairy industry.

Another result of improved storage during transport has been a great development of Empire fruit growing. Apples and oranges were formerly obtainable in England only in winter; they are now obtainable in spring and summer, thanks to the marked developments in Tasmania, the Murray region in Australia, and South Africa. Plums, peaches, grapes come in abundance from South Africa, bananas from Jamaica; not only are the total imports of fruit increasing, but also the proportion from the Empire increases; it had averaged 24 per cent for the five years 1925–29, and rose to 33 per cent in 1930; home growers supplied 26 per cent—usually their share is nearer 30 per cent. The Empire still, however, supplies less than one orange out of every four that we eat, only 39 per cent of our bananas, 16 per cent of our grape fruit, and 10 per cent of our pineapples; there are therefore considerable possibilities of further development. Demand is increasing; in 1930 the consumption of fruit per head of population in Great Britain was nearly 83 lb., as against 70 lb. in 1924. Other countries are improving their production and transport. In Great Britain, Barker, Wallace, and their colleagues at Long Ashton, and Hatton at East Malling, have greatly strengthened the fruit growers' position, and for fruit the outlook is, as for other commodities, a power of production growing greater than the power of consumption. Another important factor in the fruit industry has been the development of canning, which affords a satisfactory way of dealing with excess produce.

Engineering science has further intensified agricultural production by developments in irrigation. The greatest triumphs of irrigation in our time have been in India. The cultivable area of India has been enormously increased, and land provided for millions of peasants who would otherwise have had none.

Irrigation schemes worked by white men are so costly that only valuable products can be raised. In all cases irrigation has greatly increased the output from the land and greatly increased the supplies for the world market. If time permitted, it would be possible to go through the whole list of products of the earth and show how modern science has increased output far beyond human needs, with a resulting fall in demand and lowered prices. One could dilate on the achievements of the Dutch in Java in producing their new sugar-cane, which quadrupled the output and so lowered the price of sugar that the West Indies are in terrible distress, the sugar-beet industry of Great Britain is threatened, and all Europe would be in trouble but that they artificially keep out the new sugar. Or again, one could speak of the achievements in rubber growing, of the change over from wild rubber to plantation rubber, of the extraordinary improvements in technique, which have in the past thirty years so enormously increased the output that even the most extensive new demands of modern civilisation—rubber tyres, rubber floors—have failed to keep pace with supplies, so that the price, which in 1910 was 12*s.* 6*d.* per lb., is now reduced to 3*d.*, and may fall still lower, causing great distress to the rubber growers.

Modern science, in short, has been so successful in increasing man's power over Nature that it has brought us harvests far more bountiful than we know what to do with. Yet, although we may think in our pride that we have achieved a wonderful control over Nature, our control is really very limited, our tenure uncertain, and our margin of safety very exiguous. How long mankind will have the wit to go on developing more powers we do not know. It is quite certain that any slackening of control or failure to utilise scientific discovery by any one group of cultivators would speedily eliminate them through pressure of more enlightened and therefore more successful competitors. It is, however, not so much human competition as the opposing natural agencies that must continuously be watched. The weather can still defeat our best laid farming plans. Over large parts of our Empire there is a continuous struggle for possession between insects and men, and the margin of victory, even when we get it, is never very great.

There are also new troubles as yet only dimly seen that may easily cause great difficulty in future. The remarkable development of rapid transport has carried all over the world not only the blessings but also the evils of this earth. Pests and diseases of animals, and particularly of plants, have only to appear in one corner of the globe to spread elsewhere with great rapidity despite all regulations to the contrary, often causing enormous losses. Among the most serious troubles of modern times are the virus diseases of plants. These diseases are apparently not caused by any recognisable living organism, nor are they simple physiological disturbances; they cannot yet be attributed to any definite causal agent. They spread rapidly, being frequently carried by small insects, sometimes by mere contact, and they cannot be cured—one can only stand by and see the plants perish.

All kinds of crops are affected: sugar-cane, tobacco, cotton, sugar-beet, groundnuts, bananas, potatoes, maize, timber trees (for example, sandal), large and small fruits (for example, peach and raspberry), and most greenhouse and horticultural plants. Moreover, it is not so much sickly plants as healthy ones that suffer In Gambia the Rosetta disease cut down the crop of groundnuts to about one-third of the normal yield. In the United States in 1926 two virus diseases reduced the crop of potatoes by no less than 16 million bushels. In Great Britain the total loss cannot be estimated, but the figures recorded for various attacks vary from 35 to 75 per cent loss of crop. Worse still is the deterioration of stocks: stocks apparently healthy and vigorous may become worthless in two to four years. Cotton growers are becoming seriously perturbed. In the Gezira last year the losses were considerable, although until recently the leaf-curl disease was unknown there. Sugar-beet in the south-western region of the United States is so seriously imperilled by the curly-top disease that the Government has set aside 300,000 dollars for its investigation. In England special grants are made to Rothamsted, Cheshunt, Bangor, and other institutions to study these diseases. Tobacco is now being badly attacked, also tomatoes and potatoes; the latest sufferers are the narcissi and daffodils in our own gardens; these cease to flower and shortly perish. Virus diseases are quite recent as serious plagues; if they are old, they have hitherto been unimportant or unnoticed. Clearly, Pandora's box is not yet empty.

The United States stands easily first in elaboration of agricultural research, organised not only by the Government but also by private endowment. Both in England and in the United States, men who have made fortunes in the city have spent their money in developing agriculture or agricultural science. The America patron has spent his money on a college or research station, setting up a laboratory or some other new building, or endowing fellowships, so that a succession of vigorous young people could develop the subject, adding also greatly to their own value as workers for agricultural progress. So the gift has fructified and enriched the community in ever-widening circles. The British patron, on the other hand, has usually spent his money on his own estate, making his own experiments in farming. Some have rendered service by carrying pedigree live stock over periods of depression when the commercial farmer might perforce have had to let them go. But many have simply experimented on no very definite basis and with none of the continuity essential to the success of agricultural investigation. While, no doubt, getting much amusement out of it themselves, they have not achieved results commensurate with the time and money expended.

Without disputing the inalienable right of the Englishman to spend his money in any way he may think fit, we can still commend to the English patron the wonderful possibilities of the endowment of agricultural research. To say nothing of Lawes and Rothamsted, think what the world has gained through John Quiller Rowett's gift in 1920 of land near Aberdeen, and of £10,000 to erect buildings, thus founding the Rowett Institute. Scotland has recently had a further benefaction in the Macaulay Soil Institute set up to study the peat soils of Scotland and to help the farmers there so long as any men farm in Scotland. We remember with gratitude, and we know that our children will do so, the names of Molteno, William Dunn, Thomas Harper Adams, Charles Seale-Hayne, John Innes for their foundations in England; Peter Waite and John Melrose for the Waite Institute in Australia, William Macdonald for the Macdonald College in Canada, Thomas Cawthron for the Cawthron Institute in New Zealand. To-day the need is not so much for new institutions as for the strengthening of some of those already in existence.

Within the Empire all agricultural experts are now in touch with the central clearing houses in Great Britain, the Imperial agricultural bureaux, the function of which is to search the world for information likely to be useful and then pass it on to the persons likely to want it. The system is working well.

World organisation of scientific investigation is proceeding rapidly. Of the three factors involved in the agricultural situation, production, marketing, and the scientific advisory and technical system, the last is by far the best organised. Much has recently been done, however, in developing better and more efficient marketing by the Empire Marketing Board and the Ministry of Agriculture.

Our greatest need, however, is a better organisation of agricultural production. A beginning has been made by the overseas farmers; the necessity for sending all produce through one or two ports has compelled them to work through large organisations for grading, transporting, and selling the produce, with skilled representatives in Great Britain. Dealing in hundreds or thousands of tons, they reduce all costs and all wastage to a minimum. Gradually the British farmer is organising. But greater organisation is highly desirable. At present British farmers, Empire farmers, and farmers from all over the world indulge in deadly competition in the British market. In the end they obtain wholly inadequate prices. But the community as a whole does not gain because they lose.

Thanks to the inquiries made by the Ministry of Agriculture and the Empire Marketing Board, the food requirements of Great Britain are fairly well known. Our next great step forward will be to organise production on a contract basis so as to satisfy these requirements with a reasonable margin of safety, but without the terrible waste involved in those large excesses which injure the grower without benefiting the consumer.

Something of the sort is essential if farming is to survive as an occupation for the best of our people. Organised production and the development of the contract system which has done so much for the milk producers, would permit of a renewal and development of country life to the fullest extent now made possible by scientific and technical advances. By common consent many of the ills of to-day arise from the fact that for nearly a century the industrial side of our national life has been fostered at the expense of the rural side, producing an over-industrialised town population peculiarly susceptible to world economic disturbances, and now largely without employment or prospect of employment. The rural population, on the other hand, is far less sensitive to economic disturbances; the low rate of unemployment in the countryside shows the greater independence and resilience of the conditions of country life, and points clearly to the fact that improvements in our rural life would benefit not only the countryman but also the whole community.

Faraday and Marine Boilers.

FARADAY was probably the first man of science in Great Britain to be called upon to give advice on the working of marine boilers. There is little to show that his views affected marine engineering practice at the time, for his evidence was hidden away in a Government report which few engineers read, but it is not without interest to find that subsequent experience led to the adoption of methods the germs of which are to be found in what he said.

The circumstances in which Faraday came to be associated with the matter of marine boilers were as follow. In 1822 a Select Committee of the House of Commons was appointed to consider the question of steam navigation as relating to the communication between Great Britain and Ireland by steam. The committee, of which Sir Henry Parnell, Bt., was the chairman, became known as the Holyhead Roads Committee, and it sat when Telford was busy with the great Holyhead road and the suspension bridge over the Menai Straits. At the time the inquiry was held, ten years had elapsed since Bell's *Comet* had inaugurated regular steam navigation in Europe, and in Great Britain alone there were about 150 steam vessels afloat. Most of these were running on the rivers, but the eminent marine engineer, David Napier, had proved that steam vessels could be built for work in the open sea and had successfully established services between Dover and Calais, Holyhead and Dublin, and between Glasgow and Belfast. This success in turn led to the dispatch of mails to France by steam, and in 1821 the Post Office decided to have its own steam boats. That year, therefore, the *Dasher* and *Arrow* were built for running between Dover and Calais, and the *Royal Sovereign* and *Meteor*, somewhat larger vessels, for the Holyhead and Dublin route. As these were the first steam vessels owned by any Government department, they were regarded with great interest, and the committee of 1822 was mainly concerned with the construction, maintenance, and running of the *Royal Sovereign* and *Meteor* and other vessels which it might be decided to build.

The committee sat on various days between March 21 and June 1, 1822. Among the witnesses examined were officials of the Post Office, captains of steam vessels, and well-known engineers such as Joshua Field, Bryan Donkin, Timothy Bramah, James Brown, and others. These all gave valuable information as to the size and construction of the boats, the types of engines and boilers, the staffing of the engine rooms and such matters, but it was left to Faraday, who described himself as "chemical assistant at the Royal Institution to Mr. Brande", to enlighten the committee on the chemistry of steam raising. He had to tell the committee all about the composition of sea water, what salts it contained, what happened to the salts when the water was evaporated, what action the salts had upon iron and copper, what was the effect of incrustation, what could be done to prevent deposits forming, how fires in bunkers could be avoided, and so forth.

In 1822, and for many years afterwards, marine boilers were just great rectangular tanks with internal furnaces and flues of square or rectangular section, and they were invariably fed with sea water. The engines had jet condensers, not surface condensers, and there was no way of keeping the boiler water fresh even if the boilers were filled with shore water before starting on a voyage. As, however, the steam pressure was only about 2 lb. or 3 lb. per sq. in., by taking proper precautions the density of the boiler water could be kept down, and engineers who knew their work could keep their boilers remarkably clean. In other cases there was much incrustation, while corrosion was rampant. Iron boilers in some vessels only lasted two years, and so a good many engineers adopted copper for the material for boilers.

These facts were all known to Faraday, who had prepared a long memorandum for the committee, dated from the Royal Institution, May 7, 1822, and it was in this and in his evidence he made his many valuable suggestions. One of these was that engineers should be provided with hydrometers, another that the density of the water in the boiler could be kept down by a continuous system of brining, and a third that the action of acids could be neutralised by the use of lime, potash, or soda. If copper boilers were to be used, iron bolts and fastenings should not be used, while if there was fear of fire in bunkers it would be an easy matter to fit horizontal temperature tubes of iron through which thermometers could be passed. Many strange practices were in vogue among marine engineers in the early days. Dung, potatoes, and oatmeal were all put into boilers for stopping leaks, and other substances were used with the idea of preventing incrustation. It therefore occasions no surprise to find that Faraday was asked, "Would a dry holly or thorn bush introduced, if practicable, into the boiler take off a part of the crystallisation which would otherwise adhere to the bottom of the boiler?"

News and Views.

DEC. 12 was the thirtieth anniversary of Marchese Marconi's first successful attempt to transmit a radio signal across the Atlantic. In 1901 there were no valves, no amplifiers, no sensitive receivers, and no means of making continuous waves. All that was available for transmission was a system of damped waves produced by irregular spark discharges; the coherers then used for reception were very insensitive. In 1900 a station was erected at Poldhu in Cornwall and another at Cape Cod, Mass. In designing these stations, Marconi had the help of Sir Ambrose Fleming, R. N. Vyvyan, and W. S. Entwistle. When the

Poldhu station was nearly completed, a terrific gale wrecked the tall masts that had been erected. Although greatly discouraged, Marconi erected a much less ambitious aerial system. In November 1901 another gale destroyed the antenna system at the Cape Cod station. Marconi then determined to try aerials suspended by kites and balloons. As the letter ' s ' is easy to transmit, he arranged that a series of these signals should be emitted at a prearranged speed from the Poldhu station during certain hours of the day. After several unsuccessful trials, Marconi heard three faint clicks in the telephone at 12.30 P.M. on Dec. 12. They were also heard by his assistant. These signals led to the building of the high-power radio station at Glace Bay in 1902, and at the beginning of 1903 commercial radio communication across the Atlantic was established. Remembering that in those days physicists and mathematicians did not know of the existence of a conducting layer in the upper atmosphere, and that consequently most of them anticipated that no result would follow from these costly experiments—and did not hesitate to say so—it will be seen how much indebted we are to Marconi's pioneering work.

IN an article in the *Nineteenth Century* for December, on Erasmus Darwin, 1731–1802, the bicentenary of whose birth was referred to in NATURE of Dec. 5, Mr. H. Pearson refers to him as the greatest English doctor of his time. No one, perhaps, knew better than Darwin the futility of many of the notions prevalent, and much of his own success depended on his insight into human nature. His methods were often experimental and sometimes risky, but a man who never tried an experiment he declared to be a fool. His great originality of mind, his independence of character, and his versatility were shown in many ways, and he was every bit as interested in human progress and the sciences and arts as he was in the ailments of his patients. Wells and witches, canals and candlesticks, pumps and ploughs were only a few of the things on which he had ideas. He was certainly a pioneer in the use of electricity for medical purposes, and when Priestley discovered oxygen, he at once envisaged the submarine vessel which " Buoy'd with pure air shall endless tracks pursue ". Then, too, as Dr. Krause said, he was the first who proposed and persistently carried out a well-rounded theory of evolution. Like some of the other members of the Lunar Society, which he founded, Darwin was a sympathiser with the French revolutionists and the American colonists. Mr. Pearson gives brief biographical notes on some of the most distinguished members of that small but influential society: Keir, Galton, Wedgwood, Watt, Priestley, and others, all of whom owed something to the free and stimulating conversation of Darwin. In person, as Mr. Pearson says, he was somewhat corpulent, his face was marked by smallpox, he was clumsy in his gait, careless in his dress, and stammered excessively. Like his famous contemporary Johnson, with whom he had some resemblances, he practised an unbounded benevolence.

THE Prince of Wales was the guest at the tercentenary dinner of the Clockmakers' Company, held on Dec. 9 in Merchant Taylors' Hall to commemorate the three-hundredth anniversary of the incorporation of the Company by charter. The Master, Sir Frank Dyson, Astronomer Royal, presided. The charter was granted on Aug. 22, 1631, when the Company was styled " The Master, Wardens, and Fellowship of the Art or Mystery of Clockmaking of the City of London ". It was constituted a livery company in 1766. Though to-day the Company does not exercise the same control over the trade as of old, it serves its interests in many ways. Its library of works on horology and its collection of clocks and watches are deposited in the Library and Museum of the Corporation of the City of London in Guildhall, where they are open to inspection by visitors. David Ramsey was the first Master of the Company, while among his successors have been Edward East; the Fromantels, father and son; Thomas Tompion and George Graham, both of whom are buried in Westminster Abbey; John Harris, Daniel Quare, and Thomas Earnshaw. When proposing " The Clockmakers' Company ", His Royal Highness said that he was proud that the clockmakers had selected him, as the first master of the Master Mariners' Company, to propose the toast. There is no doubt, he said, that we have always been first in the field as regards chronometers, or machines for finding longitude. Some of the members of the Master Mariners' Company would be able to say what splendid instruments English chronometers are, and he expressed the hope that the Clockmakers' Company will continue to flourish and maintain the high standards for which English skill and workmanship have so long been renowned.

THE Humber ports are the largest fishing centre in the world and it was intended from the first that the Department of Zoology in the University College of Hull should co-operate with the fishing industry. To this end, A. C. Hardy, who served as marine biologist on the *Discovery* Expedition of 1925–27, was appointed as the first professor of zoology and oceanography in the College. A scheme for fisheries research was drawn up by Prof. Hardy and additional accommodation has now been provided by the College. The interest of the fishing industry in this development was shown by Sir John Marsden, president of the British Trawlers' Federation, when he formally opened the new department on Dec. 8. Sir John commented on the fact that, in the past, the fishing industry paid little attention to scientific investigations, partly because the industry itself consisted of a number of individual units working independently. This has now been changed and the Federation over which he presides represents ninety-nine per cent of the steam trawlers of Britain. The Federation, he said, is ever vigilant of its members' interests, and, we may add, is fortunate in having as its leader one who appreciates the importance of scientific research. Sir John commended the good work already being undertaken by Prof. Hardy and his staff, and said that even closer co-operation between the College and trawler owners would be to the lasting benefit of the fishing industry. The capital cost of the new laboratories has been borne by the College, but the greater part of the maintenance will be met by a Government grant, on the recommendation of the Development Commissioners. The work to be undertaken—in brief, the distribution of the plankton of the North Sea in relation to the movements of fish, particularly the herring—was described in an article which appeared in Nature of June 13, page 911.

The Fourth Pacific Science Congress met at Batavia-Bandoeng, Java, in 1929, with Dr. O. de Vries as general president, and five bulky volumes of proceedings—general part and reports on oceanography, physical papers (two vols.), biological papers, agricultural papers (The Hague: Martinus Nijhoff, 1930, 60 guilders)—have recently been published. The idea of conferences for the joint discussion of Pacific problems was first mooted at the meeting of the British Association in Australia in 1914, and came to fruition in the Congress in Honolulu in 1920. Eventually the Pacific Science Association was formed as a permanent organisation of the institutions and individuals engaged in research on the scientific problems of the Pacific region, and the Java conference in 1929 was the first to meet under its auspices. Discussions and papers were confined strictly to problems of Pacific interest, and agricultural science was included for the first time. The agricultural division, however, scarcely supplies any problem of circum-Pacific scope, the Pacific Ocean being in this respect rather a barrier than a link between the countries west and east of its waters, the range of climates extending from the arctic and antarctic to the tropical types, and agriculture, therefore, may find it more suitable in the future to organise along other lines.

A wide range of subjects was dealt with in the physical, biological, and agricultural sections of the Fourth Pacific Science Congress. The papers, numbering about 270, were mostly short but comprehensive, and touched on problems of fundamental and practical importance. Some twenty-six countries were represented, and the foreign members were given the opportunity of joining excursions to make first-hand acquaintance with the conditions and problems under discussion. The advantages of personal contact offered by the Congress were enhanced by the facts that a total eclipse of the sun occurred during May and the Third Congress of the International Society of Sugar Cane Technologists met during June, which brought together a number of other scientific workers, who found the Pacific Science Congress a suitable meeting-place to exchange views and results.

Dr. M. McClintock, of Harvard University, gave an interesting radio talk over the Columbia Broadcasting System on Oct. 30, on street traffic engineering. He pointed out that the safe and orderly movement of traffic over streets and highways is a great national problem in America. It is estimated that more than two million pounds are wasted annually in the United States because of the delays occurring from traffic congestion. Every year there are more than 32,000 fatalities and more than a million personal injuries owing to motor-car accidents. There is an urgent demand for the mitigation of this evil. Dr. McClintock thinks that one of the most promising remedies is to be found in properly designed motor vehicles. The modern motor-car has made great strides in this direction during the last ten years. We have now four-wheel brakes, splinter-proof glass, shock absorbers, more flexible power plants, stronger bodies, and better headlights. Statistics prove that the motor of to-day is four times safer than the motor of ten years ago, but it is not yet ideally designed to function in modern traffic. Great progress has been made in securing national uniformity in the rules of the road. In the installation of 'stop' and 'go' visual signals there is still much room for improvement. Many engineers assumed that they were a panacea for all traffic difficulties. The result is that they have been installed in many cities in places where nothing but added delay, increased risk, and irritation of the driver can result. When the problem has been properly studied and all the facts obtained by statistical researches taken beforehand, smooth running has resulted. The knowledge recently gained as to the best systems of automatic control leads to the belief that in the future there will be very few traffic policemen. It has to be remembered always that, no matter how perfect the scientific control of traffic may become, the most important element is still the human one.

In a report just issued by Steatite and Porcelain Products, Ltd., of Stourport, Worcestershire, many experiments are described which prove the value of modern research methods in improving the devices used in industry. The report discusses the design of protective fittings for the long strings of insulators used in connexion with the National Grid in Great Britain. Many have wondered why large metal rings are put at the ends of these sets of insulators. Apparently the original idea was that they would level down the voltage stresses between the individual units and thus diminish the maximum electric stress on the set. In practice the insulators when clean and dry provide an insulation far in excess of the maximum permissible. It is found that when soiled and wet the stress distribution is automatically altered for the better, and so this detracts from the usefulness of rings for this purpose. They are, however, of great use in protecting the insulators from damage when a low frequency arc occurs, as it is kept at a distance from them. Well-designed insulators withstand transient flash-overs, but a prolonged arc will damage any insulator. The report shows photographs of arcs taking place at 400 kilovolts between arcing horns, and many cinematograph and oscillograph records of arcs and flash-overs between arcing horns protecting strain insulator sets under all kinds of atmospheric conditions. These prove conclusively that the double horn type of protector serves the purpose of keeping the arc away from the insulator set and also breaks the arc. When the insulator set is used horizontally, protectors for it are much easier to design. In this case the arc is kept clear of the insulator by the convection currents of hot air. Horns in conjunction with an arcing ring were found very satisfactory. The arc started between the horns and the ring, and then rose and broke very quickly.

THE Smoke Abatement Handbook recently issued by the National Smoke Abatement Society gives a concise but comprehensive summary of information relating to smoke abatement. The numerous facts cited include data not only on the composition and deposition of soot, the production of smoke, its effect on health, vegetation, and buildings, but also on the various smokeless fuels, their production and sources of supply, together with a directory of associations, and a list of local authorities represented on the Council of the National Smoke Abatement Society. Estimates are given of the cost of smoke to various towns; for London this is given as £6,815,000; for Manchester, £2,900,000; for Birmingham, £2,350,000; for Liverpool, £2,308,000, and for Glasgow, £1,809,000. A useful summary of both the English and the Scottish law relating to smoke emission reveals the absence of any legislation concerned with the domestic smoke which is responsible for upwards of seventy-five per cent of atmospheric pollution. Other sections on industrial smoke abatement and the domestic smoke nuisance are included, in which the factors tending to produce smoke are analysed and methods of dealing with the domestic problem are outlined. The British Electrical Development Association contributes a note on "Electricity and Smoke Abatement", and a further section outlines the contribution of the gas industry. Gas coke is fully discussed, and reference is made to the new portable inset grate which facilitates its use in open fires. The measurement of atmospheric pollution is described, and also the measurement of the obstruction of light by atmospheric pollution. The booklet provides, in accessible form, information indispensable to all who may have occasion to speak or write on the subject.

THE requirements of artificial illumination for grading grain fall under three heads: (1) colour or composition of the light; (2) intensity of illumination; (3) diffuseness of the illumination. D. C. Rose (*Canadian Journal of Research*, vol. 5, p. 64; 1931) has tested various combinations of lighting units, and finds satisfactory working from two Ivanhoe Glassteel Diffuser fixtures of 500 watts each, with a 'Trutint' glass globe, and from certain arrangements of a Cooper Hewitt mercury vapour lamp, *M* Tube type, a Cooper Hewitt hot cathode neon lamp, and a General Electric Type *S*1 sun lamp. The colour of the light is, if anything, less important than its intensity and diffusion, provided it does not differ too greatly from that of noon sunlight, which is adopted as the standard white light, with a colour temperature of from 5000° K. to 5400° K. Certain precautions need to be observed by the inspectors using the lamps to ensure accuracy of grading, but if the instructions given are duly carried out, it becomes possible to grade wheat throughout the day and night during rush periods, instead of only during a few hours with ordinary daylight. Various methods of increasing the intensity of reflected light have been tried for grading wheat by physical means, but so far none has given results of any value. Chemical tests are too lengthy, and in any case the protein content of wheat does not seem to follow the grade in any regular manner. It would seem, therefore, that the only improvement in method that is possible at present is the use of artificial light for examination as indicated above.

DR. FREDERICK V. COVILLE, botanist of the United States Department of Agriculture, and chairman of the Research Committee of the National Geographic Society of America, has been awarded the George Robert White Gold Medal of Honor, the highest horticultural award in the United States, made by the Massachusetts Horticultural Society. Dr. Coville is known for a series of botanical discoveries and experiments. For example, his adaptation of the wild blueberry to the pine barrens of New Jersey has covered hitherto desolate areas with highly productive crops. Other studies he made, such as that of a method of restricting sheep grazing in national forests, have conserved vast tracts of valuable forage. Dr. Coville is joint author of "Standardised Plant Names", which gives authoritative names and spellings of 20,000 species and varieties of plants of the United States. While experimenting with the blueberry, Dr. Coville demonstrated the effect of cold in stimulating the growth of plants, and found that the wild crab, the cranberry bush, the tamarack, trailing arbutus, and the seeds of the bunchberry would not grow until chilled. He is acting director of the National Arboretum in Washington, for which the Government has already acquired 190 acres at Mt. Hamilton, and is negotiating for more. He is a former president of the Biological Society of Washington, the Botanical Society of America, and the Washington Academy of Sciences. Forty years ago he made the first botanical survey of Death Valley, publishing his findings, which ever since have been the standard work on the plant life of that region. He has also made several other botanical surveys. Other recipients of the George White medal have included Charles S. Sargent, for many years director of the Arnold Arboretum in Boston; George Forrest, of Edinburgh, who explored Tibet and western China to bring ornamental plants back to Europe; and Dr. Liberty Hyde Bailey, the well-known writer on horticulture, of Cornell.

THE extensive museum formed by Dr. William Hunter, court physician to Queen Charlotte, consort of George III., and bequeathed by him to the University of Glasgow, contains a number of specimens of insects. Particular interest and importance is attached to these, since many of them are the actual types of species founded by the great systematist, J. C. Fabricius. In order to make these Fabrician types more accessible to systematic entomologists throughout the world, it was deemed desirable that the specimens should be accurately figured and provided with up-to-date technical descriptions. This project has been rendered possible through the generosity of the Carnegie Trustees for the Universities of Scotland,

and the first instalment of the scheme has taken shape as a volume entitled "The Fabrician Types of Insects in the Hunterian Collection at Glasgow University. Coleoptera, Part I.", by Mr. Robert A. Staig, lecturer in zoology (entomology), University of Glasgow, and published by the Cambridge University Press, 1931, price 25*s.* net. This book is well illustrated by 28 three-colour process plates with appropriate letterpress. The Fabrician specimens, it may be added, are more than one hundred and fifty years old, but the great majority are still in a remarkably good state of preservation. The coloured plates and descriptions in Mr. Staig's book are based upon the actual specimens, without attempts being made to rectify defects, etc., due to age.

THE *Comptes rendus de l'Assemblée de Stockholm*, held on Aug. 15–23, 1930, for the Section of Terrestrial Magnetism and Electricity of the International Union for Geodesy and Geophysics, is a bulky volume of 479 pages. The major part of the volume consists of reports of national committees (170 pages) and communications from individuals and institutions (184 pages). Nineteen countries contribute national reports, including Germany, which was represented, by invitation, at the Assembly, though Germany does not at present adhere to the Union; among the countries not reported on are India, South Africa, New Zealand, and the South American republics; fortunately the absence of a report does not necessarily imply inactivity in this branch of science. Among the individual communications of special interest may be mentioned an account of Swedish methods of geo-electrical prospecting, and a discussion by H. W. Fisk, of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington, of the secular magnetic variation in recent years. These are among the few contributions that exceed ten pages in length, the volume being in the main made up of very short reports and papers. The portrait of the late Dr. Chree, former president of the Section, forms the frontispiece.

PROF. P. LANGEVIN, of the Collège de France, Paris, who has been in China for some time on an international educational mission on behalf of the League of Nations, has accepted the joint invitation of the National Academy of Peiping, the National University of Peking, and the National Tsing-Hwa University in Peiping, China, to give a series of lectures to physicists and advanced students of physics there. The lectures were scheduled to start about the middle of December and will probably last for one month. The subject chosen by Prof. Langevin is "Les nouvelles dynamiques de relativité et des quanta et leurs applications à quelques problèmes de la théorie du magnétisme." It is hoped that the presence of Prof. Langevin, and his lectures, will serve as stimuli to the creation of an atmosphere and an active centre for research in physical science in that region. In Peiping there are six universities having physics as a department, besides one institution purely for research on that subject. Steps are also under way towards the formation of a physical society, with its aim and its organisation along the lines of those existing in other countries.

AN interesting glimpse of primitiveness in a civilised society is afforded by a cutting from the *Age*, sent to us by Prof. W. A. Osborne, of Melbourne University. The article describes the hearing of an appeal in the High Court by the Australian Pastoral Co., Ltd., against taxation imposed by the Commissioner of Land Tax. Evidence by the general manager of the company revealed the fact that the company suffered so much from the depredation of emus in the Maranoa district that at one period head money was paid for the destruction of the birds. The company used to pay 2*s.* each for grey heads (old birds), 1*s.* 6*d.* for black heads (young emus), and 1*s.* for each egg secured. They were obliged to discontinue the payments, not because of scarcity of emus, but because the company's employees would do nothing but look for emus. The interesting feature is that the standard rate of value of emus' heads during the period of proscription led to their becoming a sort of currency. Bets were made with the heads, and they were often brought into use in the making of purchases, so that they came to be looked upon as a common means of exchange.

SIR JAMES BARRETT writes from Melbourne in reference to our article "Nationalism and Science in China" (NATURE, Sept. 19, p. 469) confirming from his own knowledge and experience the extension of Chinese anti-foreign nationalism to scientific matters. "Personally", he says, "my contact with Chinese surgeons, both men and women, could not have been more pleasant, but one cannot shut one's eyes to the intensity of national feeling." He quotes, as an example, from remarks made by a Chinese surgeon at the recent Pan-Pacific Surgical Congress at Honolulu. While cordially agreeing with Sir James in certain remarks that he had made about science having no national boundaries, he deplored the fact that for three hundred and twenty to four hundred million Chinese there were only about five thousand properly qualified Chinese medical men, and went on to say that there were in effect three medical schools only in China—the Union College, Pekin, the South Manchurian Japanese Medical School, and the Hong-Kong British Medical School.

THE *Chemiker-Zeitung* for Nov. 25 directs attention to two new reagents called 'intrammon' and 'locron', which have been introduced by the I. G. Farbenindustrie Aktien-Gesellschaft for rendering wood and various textile materials fireproof. Intrammon is used for impregnating wood, and is said to be superior to other preparations of the kind, since it can be very uniformly distributed throughout the mass of the material when applied under pressure, instead of merely saturating the outer layers. This property is due to an important constituent which the manufacturers call an activator. Intrammon provides a safeguard not only against fire but also against dry-rot and mildew. Locron, on the other hand, is applied to the surface of the material, and is not brittle like preparations containing water-glass. Under the action of radiant heat, locron swells into a voluminous, frothy crust, which acts as an insulating layer, thus protecting the underlying fibres from ignition. It can be applied to textile fibres by means of a spray.

How greatly the work of the Hawaiian Volcano Observatory is growing is shown by the appointment of two additional assistants during the last few months. In a recent *Volcano Letter* (No. 351, Sept. 17), Prof. T. A. Jaggar describes the organisation of the work at the observatory, and especially two lines of investigation on which the Volcano Association is now engaged. One is the study of the local tiltings of the ground in Hawaii in connexion with faults, earthquakes, etc., and the outlining of the boundaries of the various fault-blocks. The other is the determination of the surface-positions and depths of the foci of Hawaiian earthquakes from the duration of the preliminary tremors at three stations. The method adopted is one that has been in use for some years in Japan, but the labour of applying it is lessened by new and simple apparatus.

DR. H. R. LANG, acting secretary of the Institute of Physics, has been appointed secretary of the Institute and editor of the *Journal of Scientific Instruments*. Dr. Lang carried out research with the late Prof. H. L. Callendar, and was afterwards demonstrator in physics at the Imperial College of Science and research fellow of the Institution of Petroleum Technologists.

A SERIES of lectures on "Mycorrhiza", "Mycorrhiza in Relation to Forestry", and "Recent Researches on Tree Mycorrhiza" were given by Dr. M. C. Rayner at a number of American universities and research stations during the months of October and November. Lecture engagements at several of the Canadian universities and at various universities and research stations in the western United States were cancelled, with the intention of including them in a more extended tour during the autumn of next year.

IN connexion with the twenty-second annual Exhibition of Electrical, Optical, and other Physical Apparatus arranged by the Physical and Optical Societies to be held on Jan. 5–7 at the Imperial College of Science and Technology, South Kensington, discourses have been arranged for each evening at 8 P.M. On Jan. 5, Mr. C. C. Paterson will lecture on photocells; on Jan. 6, Mr. T. Smith will speak on photographic shutters; and on Jan. 7, the discourse will be given by Sir Oliver Lodge, on "Reminiscences".

DR. BURGESS BARNETT, who has been appointed by the Council of the Zoological Society of London to succeed the late Miss Joan Procter as Curator of Reptiles, is an old student of St. Bartholomew's Hospital. He qualified in medicine and surgery in 1915, and served as a captain in the R.A.M.C. during the War. On being demobilised, he returned to take up the post of house-physician at his old hospital, after which he was appointed medical officer to the Lobitos oil-fields in Peru. Since he has been in South America, he has collected and sent home several valuable collections of living reptiles to the Zoological Gardens. In this way he became acquainted with Miss Procter, and when on leave used frequently to help her in the treatment of difficult cases of reptilian disease. Dr. Barnett is still in Peru, and will not take up his appointment until May 1932.

WE commend to those whom it may concern, and they are many, the pamphlet on "Rats and Mice as Enemies of Mankind", by M. A. C. Hinton, issued by the British Museum (Natural History). Ten years have passed since the second edition appeared, and the third contains additional information and marks a progressive step in the national view of the rat plague, for it records the provisions of the Rats and Mice Destruction Act of 1919, which was passed while the former edition was in the press.

VOL. 2 of the *Veterinary Bulletin* will be issued monthly from Jan. 1, 1932, and will run to about 864 pages, including the index for each monthly issue and the final classified volume index. It will cover the same ground as vol. 1, but will be much more complete and will include references to all important British and foreign scientific work relating to veterinary research, administration, public health, and education. Although it was originally intended that the issues for 1932 and onwards should cover only 600 pages annually, expansion has been necessary in order to deal with the amount of material available. All communications should be addressed to the Imperial Bureau of Animal Health, Veterinary Laboratory, Ministry of Agriculture and Fisheries, Weybridge, Surrey, England.

MR. J. H. KNOWLES, 23a Beulah Hill, Upper Norwood, S.E.19, offers, in list No. 18, some two hundred second-hand books of botanical and zoological interest.

WE have received from Messrs. Bernard Quaritch, Ltd., 11 Grafton Street, W.1, a copy of catalogue No. 450, giving particulars of some 1150 second-hand works having reference to botany, agriculture, forestry, fruit-culture, gardens and gardening, herbals, early medicine and surgery, and tobacco. The catalogue is interesting and valuable in that it contains bibliographic notes on many of the volumes listed.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant at the Mining and Technical Institute and Junior Technical Day School (Boys), Bridgend—The Director of Education, County Hall, Cardiff (Dec. 22). An inspector of schools under the City of Liverpool Education Committee—The Director of Education, 14 Sir Thomas Street, Liverpool (Dec. 31). A director of education for the Urban District of Rhondda—The Clerk of the Council, Council Offices, Pentre, Rhondda (Jan. 1). A principal of the Thomason Civil Engineering College, Roorkee, India—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (Jan. 9).

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Polarisation of Downcoming Wireless Waves in the Southern Hemisphere.

In the course of experiments carried out some years ago at the Peterborough Radio Research Station of the Department of Scientific and Industrial Research, Mr. Ratcliffe and I made some observations [1] on the state of polarisation of wireless waves after their reflection by the upper atmosphere. On all occasions on which it was possible to obtain reliable measurements it was found that the downcoming waves were very approximately circularly polarised with a left-handed sense of rotation. Since it was known that the waves originally emitted by the sending stations (emitters at both Teddington and Birmingham were used) were plane polarised, with the electric vector in a vertical plane, the experiments showed that the conversion to left-handed circular polarisation had been effected by ionisation in the upper atmosphere during the process of refraction.

In attempting to explain this result it was pointed out that the influence of the earth's magnetic field is such that, for the range of wave-lengths employed (300-400 metres), there is a considerable difference between the absorption coefficients and phase velocities of the two components propagated within a refracting medium containing electric charges of electronic mass. It seemed reasonable, moreover, to suppose that the polarisation of the waves observed at the ground was produced during their emergent passage through the lower part of the refracting region. For this portion of the wave track it was estimated that the direction of propagation would not differ very markedly from that of the lines of magnetic force of the earth. For propagation along this direction the theory showed that, of the two circularly polarised components which travel, the right-handed component would be much more absorbed than the left-handed, so that waves of predominantly left-handed polarisation would emerge from the ionised layer. The account of this attempt to explain the experimental results was, however, concluded with the following sentence: "But it will easily be seen that the most direct test of the above interpretation would be to carry out similar experiments at corresponding points in the Southern Hemisphere, where the resulting polarisation should be right-handed if the effect is due to the action of the earth's magnetic field".

The Australian Radio Research Board, on its formation by the Commonwealth Council of Scientific and Industrial Research in 1929, gave the prosecution of such polarisation experiments high priority on its programme, and Mr. A. L. Green (formerly of King's College, London, and of the Radio Research Stations, Peterborough and Slough), who had assisted in the English experiments, was entrusted with the task of carrying them out. Working in New South Wales, Mr. Green was able to carry out the tests under conditions which were exactly those required for a strict comparison of results in the northern and southern hemispheres. The emitting station was situated at Coogee, Sydney, and the receiving station at a point 142·7 km. south, at Jervis Bay. For these conditions the downcoming waves must have travelled along a direction only slightly inclined to that of the earth's magnetic field. In his lengthy series of observations Mr. Green has found that all his reliable records show the downcoming waves to be approximately circularly polarised with a right-handed sense of rotation. At his request I have also compared some of his records with those obtained by us in England and have confirmed his result that, under comparable conditions, downcoming waves are polarised in opposite senses in England and Australia.

An account of the complete series of Australian experiments on upper atmospheric influence on wireless transmission will, I understand, be published in due course. Meanwhile, after having had an opportunity of comparing the records in question, I have been requested to announce this very interesting difference between the results in the northern and southern hemispheres.

Experiments on the polarisation of downcoming wireless waves are of more than scientific consequence. The home Radio Research Board, on its formation in 1920, instituted a fundamental inquiry into the cause (and, if possible, the elimination) of night errors in direction-finding. It was recognised at that time that such errors were caused by the arrival at the point of observation of waves which were abnormally polarised, but the origin of such abnormal polarisation was unknown. As a result of Mr. Green's experiments it can now be regarded as certain that the influence of the earth's magnetic field is such as to produce this polarisation. We can say that 'night errors' in wireless direction-finding are due to the arrival at the receiver of waves which leave the emitter as plane polarised waves in a direction inclined to the horizontal and reach the highly ionised regions in the upper atmosphere. There, under the influence of the earth's magnetic field, they are separated into their two component circularly or elliptically polarised waves, which undergo differential absorption and changes in polarisation and are bent round until they leave the ionised regions with a direction of propagation towards the earth. On reaching the receiver they cause fading and errors in the observed direction of the emitting station. It is also gratifying to note that, in connexion with the other aspect of the inquiry instituted by the home Board, Dr. R. L. Smith-Rose and Mr. R. H. Barfield, following suggestions of Mr. F. Adcock, have developed at the Radio Research Station, Slough, a practical direction-finder which is substantially free from errors even under conditions when downcoming waves of abnormal polarisation are being received.

Oxygen and Everest.

Dr. Raymond Greene's article [1] "Oxygen and Everest" is the substance of his contribution to the discussion following Prof. J. Barcroft's paper to Section I of the British Association at the centenary meeting, on "The Limits placed by Altitude to Physical Exercise".

In that paper it was recorded that recent experiments in the pressure-reducing chamber at Oxford have shown how work, claimed to be equivalent to ascending 1000 ft. per hour, can be done by human beings breathing oxygen, at a pressure much below that prevailing at the top of Mount Everest, 29,002 ft. The conclusion arrived at was that for the last 5000 ft. of the mountain, up and down, 700 litres or 30 cub. ft. of oxygen per man would be indispensable, involving in the containers and apparatus necessary an altogether too heavy load. The problem, therefore, of climbing Everest was deemed one less for the mountaineer than for the engineer, on whom should devolve the responsibility of devising some kind of light cylinder of high tensile strength capable of containing under great pressure the requisite quantity of gas.

I may perhaps be allowed to give in brief the substance of my remarks in the discussion on Barcroft's paper, and add one or two *à propos* of Dr. Greene's views.

Following the second expedition to Mount Everest, which was the first actual assault above 23,000 ft. on the main summit, opinions differed as to the value of an artificial supply of oxygen. Finch and Geoffrey Bruce had reached 27,200 ft. using an oxygen apparatus all the way from 21,000 ft. But Mallory's party of four climbers had also attained almost an equivalent altitude, namely, 26,900 ft., entirely without oxygen equipment and relying upon their own inherent powers of acclimatisation.

The third expedition of 1924 was equipped with apparatus of an improved kind, including three cylinders of a specially light alloy ('Vibrac') steel, with a total capacity of 1605 litres, or about 57 cub. ft. of oxygen. This amount at the prescribed continuous consumption of 2 litres per minute was to provide for a 13 hours' climb, ascent and descent. But the total weight of the apparatus was about 33 lb. This, however, was later reduced to 22 lb. by discarding one cylinder and modifying the breathing apparatus.

Owing to various defects in the apparatus, to some extent consequent upon rough handling on the outward journey across Tibet, considerable delay was occasioned by the necessary repair work before a sufficient number of apparatus were available for use on the mountain. In the meantime high camps were pitched and plans laid for attempts on the summit without breathing apparatus; and these very efforts of the climbing party were the means of bringing about a degree of acclimatisation never before attained by previous climbers. Geoffrey Bruce, who had depended on oxygen in 1922, now found no perceptible relief when using it. On one occasion I carried an apparatus up to 27,000 ft., and as I was getting no benefit at 26,000 ft. I turned off the supply of gas and continued climbing with no noticeably enhanced fatigue. By living at an altitude of not less than 23,000 ft. for 11 days a very high degree of acclimatisation had been acquired.

It must not be supposed that the failure to find relief, or advantage, when using oxygen was due, as Dr. Greene has suggested, to some inherent defect in the apparatus and its supply of oxygen to the lungs. On the contrary, every apparatus eventually repaired was in perfect gas-tight condition, and by practice a suitable habit of inhaling from the mouth-piece of the supply tube had been acquired by the users.

Acclimatisation to an altitude of 27,000 ft. has been demonstrated, and there seems no valid reasons why it should not be possible to above 29,000 ft., or the top of Everest. In their record-making ascent to 28,000 ft. and above without oxygen supply, Norton and Somervell were admittedly reduced to extremely slow upward progress, but it must be remembered that neither of them was a fit man at the outset, largely owing to their having taken part in an exhausting rescue expedition not long previously. Mallory and Irvine set out on their last tragic climb with breathing apparatus, but we may never know what benefits, if any, they derived from it. In any case, there is nothing to warrant Dr. Greene's supposition that their failure to return was due to a breakdown in the oxygen apparatus.

Our general conclusions regarding the use of oxygen were long ago stated in "The Fight for Everest", 1925, page 329, wherein it was maintained that for a mountain of exceptional altitude, such as Everest, a future climbing party might advisably be provided with a light form of apparatus supplying a sufficiency of gas for the last few hundred feet of the mountain. It was strongly recommended, however, that such apparatus should be considered an emergency measure only, and acclimatisation to the highest altitudes should be resolutely aimed at. In practice, such altitudes on Everest would be about 27,000-28,000 ft., the height of the highest camp, and one to which carrying parties must ascend, unhampered by the extra individual load of breathing apparatus. For in this connexion it should not be forgotten what a high percentage of available porterage can be consumed, as it was on the Everest Expeditions, in carrying up oxygen supplies merely for the summit climbing parties.

With these things in view, a lightened and simplified apparatus was devised in 1925, and trials of its suitability for mountain use made in Snowdonia. The equipment provided for about 15 cub. ft. of gas, and its weight was not more than 12 lb.

Thus the load involved becomes a manageable one, and from the experience gained thus far it should provide ample oxygen for emergency purposes if due regard has been given to acclimatisation. The problem of the engineer, as conceived by Prof. Barcroft, would appear, therefore, to have been already largely solved by the mountaineer, though not without the earlier advice of the former. But both engineer and physiologist may be reminded that among many mountaineers the opinion prevails that if Mount Everest and other high Himalayan peaks are worth climbing at all, they should be ascended without such artificial aids as may reduce a sport to a mere laboratory experiment. If, however, in the interests of physiology the opportunity should not be missed, where, it may be asked, can this important problem of acclimatisation be better studied than under actual mountain conditions? It would seem to be as important for study as a mere duplication of the experiments carried out in a pressure chamber, where it has been shown that man can survive, when primed with oxygen, at a pressure much below that obtaining at the top of Mount Everest.

There is, however, much besides which might with profit be investigated. Dr. Greene makes no mention of the experiments which he conducted upon himself and another member of the Kamet party, namely, dosing with ammonium chloride to counteract 'alkalosis', apparently with good results. Research into all these matters, as suggested should be undertaken by the committee appointed by the British Association, might be diligently pursued as soon as possible in order that the next Everest Expedition, whenever it may receive permission to embark again on the great unfinished task, shall have all the tried advice which physiologists can provide.

Lead Content of Rocks.

In recent years various geochemical problems have arisen which make it important that our scanty knowledge of the lead content of rocks should be amplified and made more precise. To this end we have determined the lead in a series of samples, representing in all about 220 rocks, some of which we owe to the kindness of Prof. Arthur Holmes of the University of Durham.

The sample to be analysed was brought into solution; silver sulphate was added and the silver and lead present in the solution were simultaneously precipitated as sulphide. The precipitate was then brought into solution and the lead deposited electrolytically as peroxide. That the deposit was actually lead peroxide was confirmed by a colorimetric test, tetramethyl-diamino-diphenylmethane being added to the solution of the deposit. To ascertain that the total lead content was actually recovered, we used the method of radioactive indicators. We added to the rock sample a known amount of the lead isotope radium D, prepared from radium emanation, and checked the yield obtained by measuring the activity of the lead peroxide deposit. As the purest chemicals commercially obtainable were found to contain quantities of lead that would have influenced our results, all the chemicals used were first purified from lead. Moreover, every precaution was taken to avoid contamination of the samples by dust which might have contained traces of lead. The results obtained are listed in Table I.

TABLE I.—LEAD CONTENT OF IGNEOUS ROCKS.

Rock Types.	Gm Lead per gm. Rock.
Basalt, Giant's Causeway	4×10^{-6}
Gabbros and related types (composite of 67 samples)	5×10^{-6}
Essexites and related types (composite of 40 samples)	10×10^{-6}
Shonkinites (average of 2 samples)	10×10^{-6}
Soda-granites and soda-syenites (composite of 26 samples)	11×10^{-6}
Potash-granites and potash-syenites (composite of 24 samples)	14×10^{-6}
Amphibolite, inclusion in Kimberlite, Wesselton Mine, S. Africa	15×10^{-6}
Kimberlite ('basaltic' type). Dyke from 1350-foot level, Dutoitspan Mine	16×10^{-6}
Lherzolite, Baltimore, Maryland	19×10^{-6}
Granitic rocks (composite of 58 samples of widely different localities)	30×10^{-6}
Dunite, Jackson Co., North Carolina	42×10^{-6}

The average value found is 16×10^{-6} gm. lead per gm. rock, a somewhat larger value than that given by Clarke and Steiger,[1] who found $7\cdot5 \times 10^{-6}$ gm. per gm. rock. As shown in the communication that follows, the amount of lead accumulated in the rocks since the solidification of the earth's crust (as a result of the decay of uranium and thorium) is very much smaller. Thus, as between the atomic weights of rock-lead and ore-lead we have in most cases to expect differences only in the second decimal place. That the ore-lead must have been formed in the ancestral sun, or during the events that attended the birth of the solar system, was already pointed out some years ago by Prof. Holmes.[2]

We conclude from the above determinations that the greater part of rock-lead is also of the same origin. Although acid rocks, which have a relatively high uranium and thorium content, are found to contain more lead than basic rocks, this difference is not to be interpreted as an argument in favour of the radioactive origin of the whole of the lead in rocks, but an expression of the fact that lead, like uranium and thorium, shows a marked affinity to siliceous magmas.

It is of interest to compare the lead content of basic and ultrabasic rocks with that of meteorites as determined by Noddack.[3] The lead content of stony meteorites is near that of basalt and average gabbro, and is markedly lower than that of terrestrial ultrabasic rocks. The lead content of iron meteorites, as confirmed in this laboratory, is about ten times greater than that of stony meteorites, while that of troilite (the high lead content of which was predicted by Prof. V. M. Goldschmidt) is more than a hundred times greater (700×10^{-6}). These results show that when the earth was formed the silicate shell received only a modest share of the total lead available for partition, and that this uneven distribution has so far been compensated only slightly by the formation of lead from radioactive decay.

TABLE II.—LEAD CONTENT OF BASIC AND ULTRABASIC ROCKS AND OF METEORITES.

	Gm per gm Rock.
Gabbros (average)	5×10^{-6}
Kimberlite	16×10^{-6}
Lherzolite	19×10^{-6}
Stony meteorites (average)	5×10^{-6}
Iron meteorites (average)	50×10^{-6}

[1] *Jour. Wash Acad. Sci*, 4, p. 58; 1914.
[2] NATURE, 117, 482, April 3, 1926.
[3] *Die Naturwiss*, 18, p. 761; 1930.

IN two earlier communications on this subject [1, 2] I directed attention to the bearing on geological time and geochemical problems of Clarke and Steiger's determination of lead in a composite sample of 329 igneous rocks. The amount of lead found by these analysts was $7\cdot5 \times 10^{-6}$ gm. per gm. Adopting this result as the best then available, and combining it with other data, such as the uranium and thorium contents of rocks and the atomic weights of lead from different sources, I pointed out that the following inferences could be drawn:

(*a*) that the age of the earth could not be greater than some 3200 million years;

(*b*) that the atomic weight of rock-lead should fall about midway between 207·2 and 206·9, these being the respective atomic weights of common lead (that is, ore-lead) and lead of radioactive origin generated in the rocks; and

(*c*) that ore-lead could not have been derived from igneous rocks or their magmas, since the atomic weight estimated for rock-lead, 207·05, differed widely from that actually found for ore-lead.

The third of these inferences was supported by the remarkable coincidence that in the one measurement on record of the atomic weight of a sample of rock-lead (from cotunnite, 1906 eruption of Vesuvius) the average value found was 207·05 (Piutti and Migliacci, 1923), whereas for ordinary lead the same investigators obtained the value 207·19. Nevertheless, the inference has proved sufficiently disturbing, as I hoped it would, to stimulate workers in various research centres to revise and amplify the data on which it was based. If, for example, Clarke and Steiger's figure for the lead content of rocks were not fairly representative, then the whole argument would stand in need of revision. Similarly, if the ratio Th/U in rocks were greater than 2·2, then the atomic weight of generated lead would be correspondingly higher than 206·9. Moreover, the Vesuvius magma is of a rather uncommon type, widely different from that with which lead ores seem generally to be associated. An atomic weight determination of lead from rocks of the rhyolite-andesite series might therefore be expected to throw fresh light on the problem. All these lines of attack are now under active investigation, and the results announced above by Prof. Hevesy and Dr. Hobbie may be regarded as the first fruits of the campaign.

These results show that Clarke and Steiger's figure can no longer be regarded as representative. The following table makes this clear. The age of the earth is taken as 1600 million years, and the amount of lead, Pb, generated in the material of each rock or composite sample during that time is compared with the total amount of lead, **Pb**, found by analysis. It will be seen that whereas the Clarke and Steiger figure (C. and S. average) implies that the total lead is three times the lead generated during 1600 million years, the Hevesy and Hobbie figures show that the total lead ranges from four to fifty-three times the generated lead. Dr. J. A. Smythe has recently found that a composite sample of 2950 specimens of the Whin Sill contains 24 × 10^{-6} grams of lead per gram.[3] The average contents of uranium (0·8 × 10^{-6}) and thorium (3 × 10^{-6}) are also accurately known from the work of Dr. V. S. Dubey. These results imply that the total lead in the Whin Sill is sixty times the generated lead.

Type of Rock.	U	Th.	Pb.	**Pb.**	**Pb**/Pb
C. and S. average .	6·0	15·0	2·6	7·5	3
Gabbros (average) .	2·4	5·1	1·0	4·0	4
Granites (average) .	9·0	20·0	3·7	18·0	5
Basalt . . .	1·5	1·7	0·5	4·0	8
Kimberlite . .	3·2	4·7	1·1	12·0	11
Amphibolite . .	0·9	3·1	0·5	10·0	20
Dunite . . .	1·4	3·4	0·6	32·0	53

Note.—The figures for U, Th, Pb. and **Pb** are the amounts in grams in 10^6 grams of rock.

From the point of view of the genesis of lead ores, the most significant of the results of Hevesy and Hobbie is that for granitic rocks. The latter include pre-Cambrian, Caledonian, and Hercynian granites from various parts of Europe (ranging petrographically from granite to granodiorite), and similar North American rocks of various ages from pre-Cambrian to Tertiary. In this representative composite sample the total lead is five times the generated lead. The atomic weight of the latter may be calculated and is found to be 206·96. If the atomic weight of the lead originally present in the earth be taken as 207·23, then that of the lead now present in granitic rocks should be between 207·17 and 207·18. Thus, if lead ores have been derived from granitic magmas, the atomic weight of ore-lead should vary between 207·23 and 207·17 according to the age, the higher value referring to ores dating from the beginning of geological time and the lower to ores formed at the present day. The values for actual ores should lie within these figures, and as shown in the list I have already compiled,[2] the most accurate determinations made since 1915 do, in fact, range from 207·22 to 207·18.

Thus, in the light of the new data now available, there is no longer any serious reason to doubt the usually accepted conclusion that lead ores have been derived from granitic and related magmas, always provided that the age of the earth is not considerably greater than 1600 million years. The maximum age previously calculated from Clarke and Steiger's figure for lead (on the extreme assumption that *all* the lead in the rocks has been generated within them) must now be replaced by a maximum several times higher than 3200 million years, a maximum so high that it ceases to have any immediate practical interest.

Limits of Gaseous Explosions.

It was stated long ago that the kinetics of gaseous reactions do not submit to the laws of classical physical chemistry. In particular, deviations from the law of mass action are best of all illustrated by the presence of the pressure limits for a thermal ignition.

The lower limit was revealed by Sagulin,[1] and its existence was confirmed by the work of Garner[2] and Hinshelwood[3] and others. Yet the upper critical pressure was known to Labillardiere[4] and was studied by Davy and Van 't Hoff.

However, the region of explosion between these two pressure limits has become clear only during recent years, owing to the works of Hinshelwood and Thomson,[5] and especially to those of Semenoff, Sagulin, Kovalsky, and Kopp.[6]

Recently, in the laboratory of the Institute of Chemical Physics in Leningrad, we have succeeded in establishing a complete picture of the region of explosion for a stoichiometrical mixture of methane and oxygen. It has been found that, for a certain range of temperatures, there really exist three pressure limits of ignition. The region of ignition of the above mixture in a cylindrical vessel of quartz with a diameter of 3 cm. is given in Fig. 1, which indicates the relations experimentally obtained between limiting pressures and temperatures. The lower ignition limit is represented by the curve *AB*, above which an ignition occurs. Corresponding to this part of the curve 'time lags' from 2 min. to 20 min. are observed in dependence on temperature. Curve *BC* is referred to the upper ignition limit, with the 'time lags' from 12 min. to 20 sec. Finally, the third limit of ignition is shown in the figure by the line *CD*. In this region, for an examined temperature interval, the 'time lags' are appreciably constant and equal to 6 sec. To the point *B* correspond the pressure of 6 cm. and the temperature of 650° C.; for *C*, 19 cm. and 701° C. respectively.

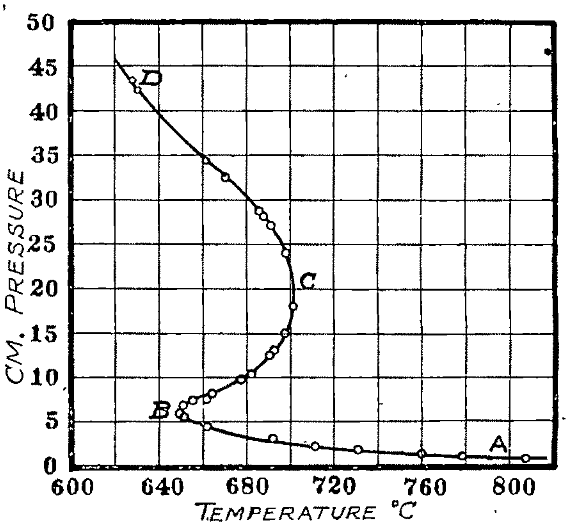

FIG 1.

The explosion is possible only to the right of the curve *ABCD*, while to the left it does not occur.

For the region of explosions between gas pressure *p*, absolute temperature *T*, and 'time lags' τ there exists a relation

$$\tau . p^n . e^{-\frac{\gamma}{T}} = \text{const.}$$

In our case $n = 1{\cdot}8$ and $\gamma = 42{,}000$.

We hope later on to give a detailed account and interpretation of the results we have obtained, on the basis of a theory of chain reactions.

In conclusion, we wish to express our sincere thanks to Prof. N. N. Semenoff, the director of the Institute of Chemical Physics, for his interest and advice during the course of this work.

The Comma Butterfly in England.

I have just seen the correspondence in Nature for Oct. 31 regarding the Comma butterfly in England, and it occurs to me that some observations I have made in the south-western parts of the country may throw some light on the increasing frequency of this insect.

About twelve years ago it was usual to see perhaps four or five specimens of the Comma each year, sunny days during early October being the time when most were to be seen, but hybernated specimens were also seen on warm days in March. During more recent years, however, the number of Commas seen has very much increased, particularly during the last three or four years, not only in Somerset, but also in Dorset and Hants as well. I have noted several occasions during the last two years, both here and in the New Forest, upon which the Comma has been quite the most abundant butterfly to be seen. I have seen as many as thirteen simultaneously on one small *Buddlea* bush in the town of Bournemouth.

What appears to me, however, to be the most striking change with regard to this butterfly lies in the fact that formerly it used only to be seen here in spring and autumn, whilst during the last three years at least it has been double-brooded in this district, numerous specimens being seen about the end of June and during July also. This double-broodedness has been confirmed by finding larvæ of both broods and also a pupa of the first brood. In addition to this, in Somerset at all events, the larvæ do not now feed exclusively on hops, but also on the common elm. The perfect insect has been successfully reared from larvæ found feeding on each of these plants. Without any special search being made, twenty-five larvæ have been found during the last two years. These observations seem to suggest that the habits of the Comma butterfly have undergone a change which may well account for the greater numbers observed during recent years.

Preservation of the Australian Flora and Fauna.

On behalf of many people and organisations who are trying to save the Australian flora and fauna, I desire to thank you for the very sympathetic reference to the preservation problem made in Nature of Sept. 12, 1931. Recently both governments and people have shown an increasing desire to try to save the disappearing animals and plants. This has been evidenced by the passing of the Wild Flowers Preservation Act both in New South Wales and Victoria, and by the extension of the Wyperfeld (Mallee) National Park in Victoria by the present Minister of Lands in Victoria, Mr. Bailey. Other proposed reservations are under consideration.

Particular acknowledgment should be made to Mr. F. Lewis, Chief Inspector of Fisheries and Game in Victoria, who has been most helpful in co-operating with various societies in the endeavour to preserve the unique creatures which at one time existed in Australia in very large numbers.

The Wyperfeld Park, situated about three hundred miles north of Melbourne, now covers thirty-six square miles of country and is one of the most interesting places on an interesting earth. The rainfall is very small, but the Park is traversed by the bed of the ancient Wimmera River, which in geological times flowed into a huge gulf of the sea in the north. The river now runs through the Park about once in ten years and then disappears in the sand north of the Park, but the water remains in the water-holes for three or four years before it evaporates. During the wet period, aquatic birds abound. Water is obtained in the dry period by wells and is used by the birds and animals. Along the bed of the river, red-gum (eucalyptus) grows profusely. Away from the river there is the usual semi-desert Mallee country. The birds nest in the red-gums, but apparently feed mainly in the outside country.

The Park is the home of the parrot and cockatoo family, which is increasing in numbers. It also contains emu and some of the black-faced Mallee kangaroo. Its profound interest is the way in which forms of life have survived and thrived in comparatively rainless conditions. The adaptation is remarkable.

Owing to the cultivation of the Mallee, the Leipoa or Mallee hen, popularly known as the Lowan, has practically been driven to seek refuge in the Park, and on a recent visit at least three of the nest mounds were found. There may have been many more, but they are not easy to find in the Mallee scrub, as there is no indication of their presence until one walks on to them.

Since the Park has been declared a National Reservation and has been patrolled, birds and animals have increased in numbers. Perhaps one of the most important features of the change is that the people living in the district have begun to take a pride and an interest in this unique portion of the globe.

Distribution of Agar-liquefying Bacteria.

Several strains of an organism which attacks and softens agar-agar have recently been isolated in this laboratory. The organism forms small, slowly growing, yellow colonies which grow well in the usual agar media; the colony is invariably situated in the centre of a circular area of softening. The 'hammered copper' appearance thus given to the plate is characteristic. No strain liquefies the agar. In stroke cultures the whole of the agar is in time softened, though growth does not proceed except on the surface.

The sources of the organisms were a swampy garden soil from Palmer's Green, London, and the clover side of Agdell Field, Rothamsted, both sampled in wet weather this spring. Most strains appear to be common to both soils. The optimal growth of most of the strains occurs in a medium containing about 0·3 per cent of sodium chloride, but one strain from Palmer's Green has grown on a medium similar to

Gran's, containing 3 per cent of salt. The presence of glucose depresses the growth of most strains.

The organisms have not been fully studied. While the finding of a halophilous organism in inland soil suggests several points of interest, the purpose of this letter is to direct attention to the probability of wide occurrence of organisms attacking agar, rather than to create new species. Such organisms have already been found in the Norwegian and West Indian seas, in Dutch soil and canal water, on Polish beetroot and Spanish raisins, and elsewhere. It seems likely that the discovery of bacteria able to attack hemicelluloses awaits but the search.

In view of the fact that such organisms have not been found here on thousands of 'count' plates, made directly from soil suspensions, it may be of value to mention that the present organisms, as some others have been, were isolated from filter-paper strips in the course of a search for cellulose-decomposing bacteria. With these latter the agar-liquefiers were frequently associated.

Periodic Precipitation in the Absence of Colloids.

Several writers[1] have recently discussed periodic precipitation in the presence of gels and other related phenomena. It is the object of this note to direct attention to one of the most important and significant papers[2] in this field that appears, however, to have been overlooked.

Morse and Pierce[3] indicated in 1903 that periodic precipitation and formation of Liesegang rings is not dependent upon the presence of a jelly. In his beautiful experiments described, with many photographs, in 1930,[2] Dr. H. W. Morse summarises his work of the intervening years and demonstrates the formation of Liesegang rings in pure aqueous inorganic substances. One of the most interesting is the series of rings of an alum, each ring consisting of a single branched crystal of the moderately soluble salt. Morse was able to explain his results without invoking anything more mysterious than the ordinary laws of diffusion and the very rapid increase in instability as supersaturated solutions rise in concentration.

Some of the first-named writers had queried the formation of rings of silver chloride in the presence of gelatine. It is interesting that this is one of the substances which Morse has photographed in periodic stratification as formed even without gelatine.

Bands in the Spectrum of Barium Hydride.

In the last few years our knowledge of the spectra of diatomic hydrides has been greatly increased. This is especially true for the hydrides of the elements in the second column of the periodic table, the spectra of the neutral molecules BeH, MgH, CaH, ZnH, CdH, HgH, and of the ionised molecules BeH^+, MgH^+, ZnH^+, CdH^+, HgH^+ having been analysed. It therefore seemed worth while to complete the available information by studying the spectra of SrH and BaH.

Bands probably due to BaH have already been reported by Eagle,[1] who used an arc in a hydrogen atmosphere between electrodes containing barium chloride. The dispersion of his spectrometer was, however, rather small. I have succeeded now in producing these bands with such intensity that it was possible to photograph them in the first order of a 6 m. concave grating. The source was a vertical arc, the lower negative electrode made of nickel having the shape of a small oblong tub, containing metallic barium, while a nickel rod formed the upper positive electrode. The arc was enclosed in a cylindrical metal case containing hydrogen; the optimum pressure was about 4 cm.

Four distinct band-heads were found at λλ 6634, 6689, 6850, 6923 A. respectively, all shaded towards the violet. The values are in agreement with the measurements of Eagle. An approximate calculation from the perfectly resolved bands furnished a moment of inertia which fits in well with the moments of inertia for elements in the second column of the periodic table, if these bands are ascribed to BaH. The electronic transition is of the type $^2\Pi - {}^2\Sigma$ and probably is analogous to the similar transitions observed in the spectra of the other neutral molecules mentioned above. A full analysis of the spectrum will be published elsewhere.

Matter: Life: Mind.

In denoting matter, life, and mind as 'events' or 'grades', General Smuts struck a happy medium between the physicists' 'stages' and the metaphysicists' 'planes'. In neither stressing nor denying a causal connexion, he succeeded in steering clear between the dangers of scientific uncertainty and meaningless profundity.

However, Prof. Boycott's letter in Nature of Oct. 24 on this subject calls for some comment.

There will be but few dissentients in answering his query in the affirmative. But where are those 'mechanists' and 'organicists' whom Prof. Boycott saddles with assigning a quantitative relationship between matter and life? Who attributes a quantitative relationship between the combined effect of life-functions and the heterogeneous and variable system of organised matter? I submit that in the present state of our knowledge the connexion between life and living matter is *qualitative*—the former being the find and determined by the complexity and organisation rather than the mass of the latter. As to the functions by which life is perceived, we can resolve them into form, growth, orientation, and reproduction. Our physico-chemical and photoelectric experience enables us to understand and even reproduce the functions of form, growth, and direction,[1] and there is but little doubt that our research in the domain of optically active substances and radioactive isotopes will give us ere long an insight into the problem of reproduction.

As already mentioned, the functions of the living unit are related in general terms to the complexity of its organisation. In the case of viruses these functions are reduced to a minimum, with a correspondingly simplified assemblage of matter essential only to reproduction.

Research Items.

Serpent Worship.—Mr. Wilfrid D. Hambly, assistant curator of African ethnology in the Field Museum of Natural History, Chicago, has made a study of serpent worship in Africa which appears as *Publication* 289 (vol. 21, No. 1 Anthropological Series) of the Museum. The study of serpent worship hitherto has been confused, but a classification of the ideas which it embodies is suggested. (1) Python worship, of which there are two unquestionable areas, one in West Africa and a smaller region in Uganda; (2) the serpent in relation to fecundity, transmigration of souls, and totemism; the only one of these with a clear geographical distribution being the reincarnated ancestor concept, which occurs continuously from the Cape to Lake Rudolph; ideas of transformation are spread over the whole continent; (3) the rainbow snake, that is, a number of stories and legends relating to snake monsters of which the basic thought is that the snake is a guardian of water, woods, ruins, or grain; (4) immunity and snake-medicines, dependent on the idea of a human soul being in communion with the snake. Evidence relating to cures of snake-bite show that the treatment is by no means entirely magical. The examination of African python worship in relation to cults and beliefs from other parts of the world provides no evidence that Africa received snake worship from extraneous sources, nor is there more than a superficial resemblance between the snake beliefs of Africa and ancient Egypt. The most fundamental ideas of all kinds of African snake belief are those of reincarnation and fecundity. The idea of the snake ancestor visiting the dwelling has a strong and clearly defined distribution from the Suk to the Zulu. Sometimes the visiting snake ancestor announces a conception. In other cases conception is inferred from the visit of any snake.

Man and the Primates.—In the *Scientific Monthly* for November, Prof. Adolf H. Schultz sets out in detail results of some of the less widely known and quite recent comparative studies on certain features pertaining chiefly to primates and their bodily proportions, which answer such questions as why the gibbon and anthropoid apes must be regarded as man's nearest relatives; whether the gaps between man and the recent anthropoids are relatively large or small when measured by the scale of differences between other primates and the like. Significant features are examined in turn. There is a tendency to increase in bodily size with advance in evolutionary development. Anthropoid apes are the only primates as large as or larger than man. Man's relative hairlessness is not unique, but an extreme manifestation of an evolutionary trend to reduce the coat of the larger primates. The nose supports the recapitulation theory. The human ear resembles most closely that of the gorilla. Man has relatively the largest head, the lower catarrhines the smallest. The high forehead of early stages of life disappears soon after birth in the apes, but is retained in man. The trunk of the higher primates has become relatively shortened by the elimination of vertebræ, allowing the pelvis to shift towards the chest, while it has become relatively short and broad. In this respect man is the missing link between apes and gibbons. In length of arm the apes, other than the mountain gorilla, have specialised to a much greater extent than man, while in length of leg man has specialised to a greater extent than the apes. The hand of man is in every respect the hand of a primate, though in breadth it is conservative when compared with that of a gorilla. The foot of man is nothing but a modification of the foot which has given rise to the foot of modern anthropoids. It is concluded that man and the large anthropoids represent the most advanced expression in all primate evolution. In some respects man is more specialised than the apes, in others the relation is reversed.

Structural Features of the Cruciferous Flower.—Two papers on the anatomical structure of normal and abnormal flowers of Cruciferæ, by Dr. Agnes Arber (*New Phyt.*, vol. 30, 1931), represent a type of investigation that is much needed to elucidate flower structure. So much of the discussion on floral morphology is based on dissections that it is time that the facts were tested with more detail and exactitude. The author is obviously not in agreement with E. R. Saunders' view of the cruciferous gynœcium, and she discusses many of her facts in relation to this argument. The fact that the placentas receive most of their vascular supply from the valve strands appears to support the bicarpellary view, but it is also shown that the lateral sepal bundles are derived from the petal bundles, showing that "vascular bundles may exhibit a complete disregard for morphological boundaries", and this makes the origin of the placental bundles carry less weight than might otherwise be the case. It would be most interesting to know the anatomical facts for the gynœcium of the two species of *Triglochin*, which would appear to be more obvious illustrations of E. R. Saunders' theory. Of less controversial nature, it is satisfactory to have confirmation of Klein's observation that the strands to the lateral sepals pass out before those of the median, thus bringing the cruciferous flower into line with the general rule for the origin of the outermost foliar structures on lateral flower or vegetative buds. The vascular supply to the inner stamens does not support the suggestion of chorisis. The squamules found in relation to young leaves and pedicels (especially in *Nasturtium officinale* R. Br.) are suggested to be "stipules of non-existent bracts". The general absence of stipules in cruciferous leaves makes one sceptical as to the stipular interpretation, though bracts may occasionally be seen subtending the lower flowers in *Cheiranthus* or *Capsella* and probably other genera also.

X-Ray Analysis of Slate.—An application of the X-ray diffraction method to the elucidation of the real nature of slate has been made by H. V. Anderson and K. C. Chesley, and their results and conclusions are presented in the *Amer. Jour. Sci.*, August 1931, pp. 103-112. Seven slates from different localities were examined, and a table is given showing the interplanar spacings in angstrom units, as obtained by the powder method, together with the principal spacings for the minerals found to be present. Evidence is forthcoming which indicates that former analyses reporting kaolin or andalusite in slate are in error, and that the probable aluminium silicate present is kyanite. The preponderance of quartz, corundum, kyanite, and mica in slates is established, and small quantities of other minerals are indicated. An attempt is made to correlate structural differences with grain size, and further work along this line is in progress. X-ray analysis confirms the fact that the cleavage is due to the orientation of the mica during its crystallisation under pressure.

Light Transmission through Fog.—Owing to the increasing importance of commercial aviation, much experimental work is being done on the transmission of visible light through fog. In the *Physical Review* for July 1931, H. G. Houghton gives an interesting account of experiments in this connexion which he has made. He produced a fog by condensing low-pressure steam in a zinc-lined wooden chamber 300 cm. long and 25 cm. square. At one end was located the source of light—an incandescent lamp—and the necessary optical systems and filters for obtaining various bands of wave-lengths in the visible spectrum. The detecting apparatus consisted of a photoelectric cell, a two-stage direct current vacuum tube amplifier, and a sensitive milliammeter. The only difference between the artificial fog and natural fog was the size of the fog droplets. It was found that the artificial fog was composed of smaller particles of more uniform size. After some difficulty, a cell was obtained which was sensitive over the entire visible spectrum. It was found that no type of visible radiation possesses any very marked fog penetrating powers. The coloured beam of wave-length $0{\cdot}490\mu$, however, transmitted a definite maximum percentage of light. The author concludes that the attenuation is probably due more to scattering than to absorption. The shape of the curve showing the transmission at various fog densities indicates that it is largely dependent on the size of the particles of the fog used. Hence any transmission curve is applicable only to the particular fog on which the measurements were made. The author's results apply only to a fog or haze where the particles are small. In the same journal, in conjunction with J. A. Stratton, it is proved mathematically that the particle size of the fog is a controlling factor in the transmission characteristics.

Abnormality of Radio Signals passing through High Latitudes.—Modern developments of short wave wireless communication have brought to light many interesting phenomena, such as the existence of round-the-earth echoes and echoes of long delay. Another peculiarity of such high-frequency transmission has recently been reported to us by S. Namba from the Electrotechnical Laboratory, Ministry of Communications, Tokyo, Japan. It has been noted that the signals from the New York stations received in Japan exhibit certain peculiarities which are probably attributable to the fact that the great circle passing through New York and Tokyo traverses auroral and polar regions. The New York signals are characterised by a continuous fluctuation in carrier wave frequency and a marked blurring in audible morse reception. Since it is known that the frequency emitted by the sending station is kept constant within narrow limits by piezo-electric control, the observed fluctuations in the received signal must be attributed to the influence of the transmission path. The variations in the frequency of the carrier wave are attributed to a pronounced Doppler effect, which has already been noticed to a lesser degree on signals arriving in other directions. As the main ionising agent in the polar regions is considered to be charged corpuscles shot out from the sun and deflected to the magnetic polar region under the influence of the earth's magnetic field, the ionisation in the polar atmosphere may be expected to exhibit greater fluctuations than that in non-polar regions where the main ionising agent is ultra-violet radiation. Both Doppler effect and blurred signals may therefore be abnormally marked for signals passing through high latitudes.

Quantum Theory of Electrolysis.—A new application of the quantum theory has been made by Dr. R. W. Gurney in a paper in the November issue of the *Proceedings of the Royal Society*, entitled "The Quantum Mechanics of Electrolysis". The fundamental idea in this is that the quantum mechanics does not require the same intimate contact between particles for a transfer of charge between them that is pictured on classical theory. This conception has already been employed in several problems, such as those encountered in connexion with the neutralisation of positive ions at the cathode of a discharge tube, and is here applied in particular to the electrode phenomena in solutions to which a potential less than that required to effect decomposition has been applied. Bowden and others have recently made a careful study of the small currents which pass under such conditions, and have embodied the results of their experiments in a number of simple relations. By modifying the theory of neutralisation at a gas-solid interface to allow for the hydration of the ions and other effects peculiar to electrolytes, Dr. Gurney has now been able to obtain all Bowden's results theoretically, and to obtain both qualitative agreement and excellent numerical values for the coefficients in Bowden's expressions. Dr. Gurney has actually developed his theory as if the hydrated ions were molecules in the spectroscopic sense, but this specialisation of the problem is a matter of convenience and not a necessary feature of his work.

Combination of Hydrogen and Oxygen.—When a mixture of hydrogen and oxygen is exposed to a hot quartz surface a reaction occurs which is gentle or explosive according to the conditions of the experiment. W. L. Garstang and H. L. Hinshelwood have given an account of some investigations on the kinetics of the change when it is catalysed in this way in a paper published in the November number of the *Proceedings of the Royal Society*. They have been able to show by a few relatively simple experiments that the active centres on the solid, which are responsible for much of what occurs, are chiefly concerned with the reacting oxygen in the first instance. The centres have, in fact, been shown to absorb oxygen with great rapidity to a kind of saturation state, whereas they remain only sparsely populated with hydrogen. If an aluminium vessel is substituted for one of quartz no low-pressure explosion occurs, but a vigorous reaction still takes place on the surface.

Artificial Rubber.—The production of artificial rubber by the chemists of the E. I. du Pont de Nemours is announced in the November *Journal of the American Chemical Society*, some additional details being given in the news edition of *Industrial and Engineering Chemistry*. The process depends on the addition of hydrochloric acid in aqueous solutions containing cuprous and ammonium chlorides, to monovinylacetylene, with the production of chloro-2-butadiene-1,3 according to the equation :

$$CH{\equiv}C{-}CH{=}CH_2 + HCl = CH_2{=}CCl{-}CH{=}CH_2,$$

the product (which is closely related to isoprene) being called chloroprene. The chlorine atom in the molecule is very firmly bound. By the controlled polymerisation of chloroprene, which takes place very rapidly and easily, a rubber-like material is obtained to which the trade name 'duprene' is applied. This is the synthetic rubber. Although the cost of production of duprene will be many times greater than the present market price of natural rubber, the material is to be manufactured, since it is believed that commercial uses will be found for it because of its unique properties. The material formed by the polymerisation of chloroprene is fully vulcanised without any additions, and the polymerisation can be stopped at an intermediate point with the production of a plastic polymer having the general properties of unvulcanised rubber, which may be mixed with fillers, diluents, etc., and the vulcanisation completed by heating at 110°-130° C. for a short time. An artificial latex was also prepared. Duprene is denser and more resilient than natural rubber, but is not plastic. It resists the action of many liquids which attack rubber. The X-ray structure of stretched duprene, unlike that of polymerisation products of isoprene, resembles that of natural rubber, giving a fully developed fibre diagram showing a number of definite layer lines, the identity period along the fibre axis being 4·8 A., identical with that of β-gutta-percha.

Saccharification of Wood.—In a communication to the Society of Chemical Industry on Nov. 1, Drs. H. A. Auden and W. P. Joshua described a process for the transformation of wood cellulose into fermentable products on an industrial scale. With an improved method they have succeeded in obtaining thirty-five to forty gallons of alcohol per ton of dry sawdust. This makes the process commercially profitable where the cost per ton of dry sawdust is not more than five shillings and a supply of 200 tons per twenty-fours hours is available. The method was worked out in the Research Laboratory of the Distillers' Company, Epsom. It consists in forcing acidulated water (containing two parts per thousand of sulphuric acid), at a temperature of 180° C. and twelve atmospheres pressure, through sawdust packed in lead-lined vessels. Under these conditions 45-50 per cent of the sawdust is changed into fermentable sugars. The molasses thus obtained are fermented with yeast in order to obtain alcohol. A preliminary treatment of the sawdust with superheated steam has been found advantageous, because it removes resins and other undesirable constituents and also helps the hydrolysis.

Extensibility of Protoplasm.—A communication on the effects of salts on the extensibility of protoplasm, by Prof. William Seifriz and Janet Plowe, appears in the *Journal of Rheology*, vol. 11, No. 3 (Easton, Penn.). The elastic properties of protoplasm are important because of their close relation to other properties of living matter, for example, imbibition, contractility, and structure, and to biological processes like cell-division and amœboid movement. By means of the microdissection method Prof. Seifriz has determined the maximum distance to which protoplasm can be stretched. Strips of the upper epidermis of the bulb scales of *Allium cepa* were first placed in aqueous solutions of the nitrates of potassium, sodium, calcium, etc. Afterwards the cells were plasmolised in sugar solution so that the cell-wall could be cut without injuring the protoplasm, and the protoplasm was drawn out by means of the micro-needle. It was found that treatment with calcium, strontium, and magnesium increases the elastic limit of the protoplasm, while potassium, sodium, and lithium decrease it. Their relative action may be expressed by the series $\mathrm{Ca}>\mathrm{Sr}>\mathrm{Mg}>\mathrm{K}>\mathrm{Li}>\mathrm{Na}$.

Astronomical Topics.

Eclipse Observations and the Einstein Shift.—Prof. E. Freundlich gave an account of his observations of the Einstein bending of light by the sun's gravitation at the meeting of the Royal Astronomical Society on Dec. 11. Notes on a similar lecture delivered at Oxford on Dec. 2 appeared in Nature of Dec. 12, p. 993. Prof. Freundlich was probably the very first to attempt observations on the problem; he went to Russia in August 1914 with that end in view, but the outbreak of war caused obstacles to be put in his way, and nothing could be done. Abortive attempts were made at subsequent eclipses; at last he attained full success in Sumatra in the eclipse of 1929. Many precautions, suggested by the experience of others, were taken; in particular, a field of stars at a distance from the sun was photographed during totality, as well as the eclipse field; the two fields were again photographed simultaneously at a later date.

The measures and reductions were made in several different ways, but all agreed in giving a shift at the sun's limb of about 2·25″, which is half a second greater than the Einstein theoretical value. Freundlich also rediscussed the measures made at previous eclipses, and expressed the opinion that they are better satisfied by his value than by the Einstein one, and that the excess is a real phenomenon, though its cause is unknown.

Most of the speakers in the discussion showed unwillingness to depart from the Einstein value; Sir Arthur Eddington, however, admitted that the views of the nature of light that are now held make it more complicated than was formerly supposed, so that it is possible that the Einstein equations may not give a complete account of its behaviour.

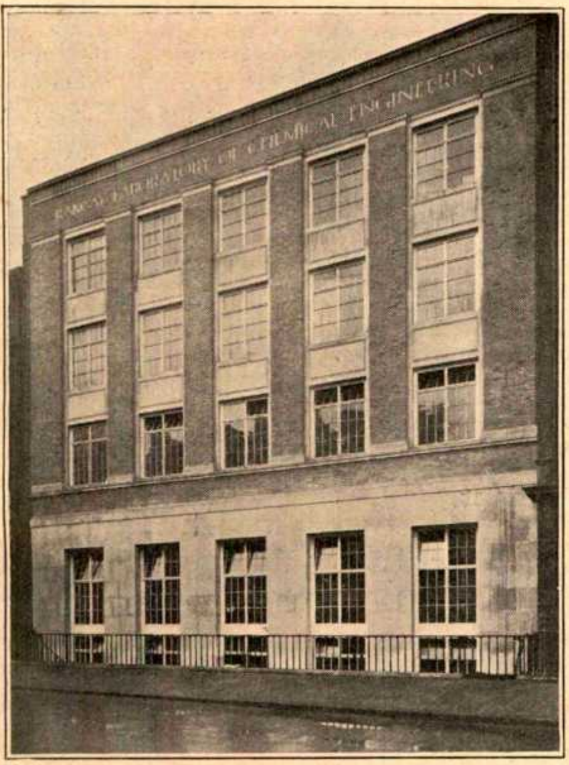
The Origin of Comets of Short Period.—About half a century ago, R. A. Proctor pointed out that the theory of the capture of these comets by the giant planets involved many serious difficulties. There would not be enough close approaches of comets to Jupiter to provide it with such a large family of comets. This is still more the case than Proctor realised, since convincing proofs have been deduced that the life of these comets is short (of the order of a few centuries), so that the supply must be frequently replenished.

Very few astronomers have supported Proctor's view that these comets were erupted by the giant planets, but *Astr. Nach.* 5826 contains a long paper by S. Vsessviatsky which reaches a similar conclusion, and extends the suggestion to include those of the minor planets that have orbits close to that of Jupiter. Many American astronomers favour the suggestion that minor planets are associated with comets in their origin. One of Proctor's arguments was based on the Leonid meteors. Le Verrier had suggested that Tempel's Comet, which formerly contained the meteors, made a near approach to Uranus in A.D. 126, and had its orbit changed from a parabola to an ellipse. Proctor pointed out that an extremely close approach to Uranus would be necessary, and that the cometary mass would need to be condensed to an extent far beyond what we observe in comets; otherwise different portions of it would experience different perturbations, whereas observation shows that the orbits of all the meteors are nearly identical.

Catalogue of Double Stars.—A further instalment of the large catalogue of double stars that is being formed at the Union Observatory, Johannesburg, is published in *Circular* 85 of the observatory. It contains 2017 measures of 488 pairs made in the years 1928–30. The limits of Right Ascension are 13^h to 24^h. As a rule, measures of each star were made on four nights, the separate results and means being given. There are interesting notes on sixty-five pairs; five of them are proved to be merely optical pairs, but the great majority are true binaries. Other notes give comparisons with previous measures, or with ephemerides, where these have been calculated. The pair Innes 600, in south decl. 60°, may have the short period 14 years, or 28 years if the quadrant of the 1913 measure should need reversal. The pair Hussey 298 has described nearly a revolution in thirty years, but apparently its orbit has not been computed yet. A note on α Centauri states that photography gives better results than visual measures; the recent measures give as the correction to Finsen's ephemeris, published in 1926, angle $+0{\cdot}30°$, distance $-0{\cdot}08''$. The great majority of the measures in the catalogue were made with the 26-inch refractor, but a few were made with the 9-inch.

The Ramsay Memorial Laboratory of Chemical Engineering at University College, London.

THE opening of the Ramsay Laboratory of Chemical Engineering by His Royal Highness Prince George, on Nov. 26, marks an important advance in the scientific training of men for industry.



Photo] [Larkin Bros.

FIG. 1.—Ramsay Laboratory of Chemical Engineering.

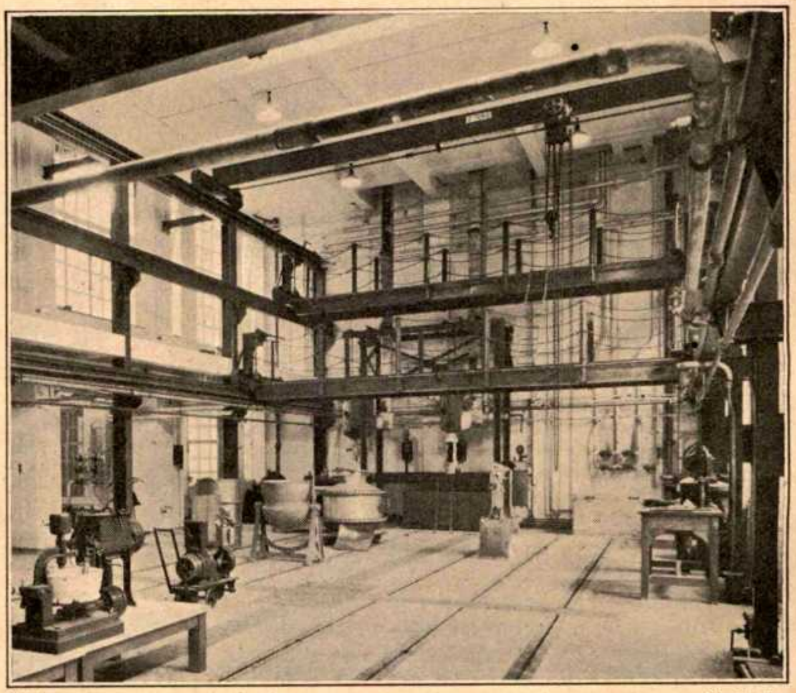
The new laboratory is the first in Great Britain to be designed specifically for chemical engineering training and research. It provides facilities whereby men who have already graduated in chemistry or engineering can obtain a supplementary training, both theoretical and practical, in the principles underlying the design, fabrication, testing, and operation of the different types of plant which are used in the industrial operation of a chemical process.

The course of training normally occupies two years. During the first year, the student receives a systematic training in chemical engineering principles by means of lectures and relevant experimental work. The subjects dealt with include the flow of fluids and the transfer of heat, the physical and chemical characteristics of construction materials and the methods of plant fabrication, the principles of mechanical and structural engineering and the production and distribution of energy in works, the design and operation of unit types of chemical plant, the preparation of flow sheets of materials and energy balances, and the lay-out of plant, factory administration, and industrial economics. The lectures are supplemented by practical training in machine drawing, in plant fabrication, and in the erection, testing and operation of both small and semi-large scale plant units.

During the second year, the student carries out original investigations, either in the laboratory or in a works.

The new laboratory (Fig. 1) has been built as an extension to the old building, which, in addition, has been completely rearranged. The laboratory now occupies a frontage of 60 ft. on Gordon Street, from which it extends for 120 ft. in the direction of the chemistry building. The new building is constructed of steel and reinforced concrete, and is faced with 2-inch Suffolk brick and Portland stone. It consists of five well planned and appointed stories. A noticeable feature of every room is the generous lighting provided by the large and well planned windows.

In its arrangement and equipment, the building presents many new features. In addition to the usual lecture-room, library, and general laboratory facilities, there are a finely equipped machine shop, in which semi-large scale plant can be constructed or repaired, and a large and lofty industrial laboratory (Fig. 2) which is well equipped for the erection, testing and operation of semi-large scale plant. Special laboratories are provided for distillation, for the testing of fuels, and for crushing and grinding operations. The second floor is devoted entirely to the study of fluid flow and heat transfer on a scale which is comparable with that obtaining in works practice. On the top floor are three research laboratories, each of which is capable of accommodating five or six workers.



Photo] FIG. 2.—Industrial laboratory. [Larkin Bros.

At the rear of the building and just outside the machine shop is an unloading bay, served by a two-ton travelling crane, which can deliver heavy goods either into the machine shop or through trapdoors into a wide service corridor which runs through the basement to the industrial laboratory.

Perhaps the most striking feature is the industrial laboratory, which occupies practically the entire basement of the new section. This laboratory is 60 ft. long, 40 ft. wide, and 25 ft. high. It is equipped with a two-ton travelling crane, and is spanned by two portable platforms, respectively at 11 ft. and 17 ft. above the floor-level. The concrete floor is provided with special slots to facilitate the fixing of plant; there are also ample drainage facilities. Staging is provided at one end of the laboratory for liquor stock tanks and feed tanks.

Five thousand gallons of softened water can be stored beneath the basement floor, whence it can be pumped to large service tanks on the roof. From there, it can flow by gravity to two 3-inch ring mains surrounding the industrial laboratory, or to the fluid flow laboratory on the second floor. This water can be used as boiler feed or for cooling or condensing purposes. Other ring mains are provided in the industrial laboratory for mains water, gas, steam and compressed air.

Steam for process working is obtained from a vertical boiler, arranged for oil or coke firing, and capable of evaporating 600 lb. of water per hour at pressures up to 200 lb. per sq. in. Two smaller boilers are provided at different points in the building.

The machine shop measures 45 ft. × 18 ft. × 25 ft. high, and is situated in the basement of the old building. It is fitted with a one-ton travelling crane, and contains the machine tools necessary for turning, milling, slotting, shaping, drilling and sawing. Running along one side of the shop is a gallery equipped with precision lathes and sensitive drilling machines for fine instrument making. There is also equipment for welding and small forging.

The erection and equipment of the new laboratory have been made possible by the far-sighted generosity of a number of leading firms and individuals in the chemical and allied industries, who subscribed a capital sum of more than £26,000 and guaranteed an annual income of £4000 for a number of years. Valuable equipment has been provided by many manufacturers of chemical plant.

The laboratory will accommodate fifty students and research workers. This session, the total number of students in the laboratory is thirty. In its organisation and general atmosphere, the laboratory seeks to resemble the development department of a modern chemical works. Every effort is made, also, to maintain and develop the closest connexion with industry. Each member of the staff has had extensive industrial experience both in Great Britain and abroad. Many of the present students, also, have held important positions in industry.

Psychology and Organised Religion.

THE *Journal of Social Psychology* (vol. 2, No. 4) has an article by Prof. Raymond Pearl discussing some points of psychological interest arising out of the American Census of Religious Bodies, 1926. His aim is to see if any evidence, other than that of general opinion, exists to support the view that there has been for some time past a gradual decay of religious influence in European civilisation. He quotes from an eminent man of science, a Wesleyan minister, a Church of England vicar, and a young American clergyman, all of whom maintain that there is increased indifference to organised religion.

If this is so, then here is a problem of social psychology that ought to be studied. Prof. Pearl makes a beginning by analysing such official returns as are available, namely, those provided by the census of religious bodies in the United States. This is a census of religious organisations and is taken every ten years.

During the period 1916–26 the tables show that while church membership has increased at a rate slightly more than the rate of the growth of the population as a whole, yet the increase is very small. It has always been recognised that religious organisations have played an important part in the social life of their members, being at some periods almost the only means of organised social diversion. Hence it seems pertinent to compare the growth of religious organisations with the growth of other forms of social activity. National banks have increased at rather more than three times the rate of the churches, the consumption of alcoholic liquor increased by 4·5 per cent in one year, the manufacture of playing cards by 80·3 per cent, and cigarettes by 97·4 per cent, and still greater was the development of motion-pictures, automobiles, and radio apparatus. It looks as if several non-religious forms of diversion grew in magnitude and presumably in influence during the decade considered.

Again, organised religion has always realised the importance of training the young, and for this end has evolved the Sunday School. Analysis of the records shows that in the older and more highly developed sections of the country the number of scholars has either decreased or increased by an insignificant percentage, whereas in the newer and less developed sections of the country there have been substantial increases. Comparing the membership of the different denominations, a tendency is shown for those characterised by a narrow and rigid body of doctrine, and therefore appealing to the less intelligent groups of the population, to grow more rapidly than those the more liberal doctrines of which appeal to the more intelligent.

The paper is important, not so much for the generalisations, which are admittedly tentative, as for the method employed and for the interest of the point of view.

In *Human Biology* (September 1931), John R. Miner discusses the relationship between church membership and commitments of prisoners. From data available from the Netherlands and the United States, he concludes that there is little evidence that the churches play any large part in the prevention of crime.

Orbit and Mass of Pluto.

LICK Bulletin 437 contains an exhaustive study by Dr. E. C. Bower, of Pluto, the new planet discovered in 1930. All the prediscovery images have been utilised, except those obtained on Flagstaff plates in 1915. Reference is also made to a possible image on a Franklin-Adams plate taken in 1903. Mr. P. J. Melotte, who detected this image, now considers that it is too ill-defined and doubtful to use, in the absence of any confirming images in neighbouring years. The perturbations have been treated in the manner adopted by Dr. P. H. Cowell for Halley's comet. The centre of gravity of the sun and the four great planets is taken as origin, and the motion calculated by mechanical quadratures. The final residuals of Pluto are all less than 4″, which is not unduly large, as in many cases the images were ill-defined and far from the centre of the plate. The period is 248·43015 years, and the eccentricity 0·2486438 (it is an aid to memory that the first three digits in these two elements are the same); the perihelion passage is on Sept. 30, 1989. There will not be a conjunction with Neptune at minimum distance (3 units) for about eight thousand years.

The determination of Pluto's mass from Neptune depends largely on the two observations made by Lalande in 1795. As he observed the Right Ascensions to the nearest half-second of time only, they are not exact enough to give a precise result; it is shown that a mass of Pluto, 1·3 times the earth's, gives a zero residual in 1795, while a zero mass makes the 1795 residual 9″. It will, however, be possible to derive a fair value of Pluto's mass from its recent approach to Neptune, when the latter has been observed for some eighty more years, as its orbit will then be known independently of Lalande's positions. Dr. Bower suggests that the approach to Uranus in 1968 (distance 13 units) should also be utilised; for this purpose a long series of accurate positions of Uranus, especially from 1940 to 2000, should be obtained. He suggests photography, with the magnitude of Uranus reduced to that of the comparison stars.

The only estimates of Pluto's mass that can be made at present are based on its stellar magnitude and apparent diameter; these both suggest a mass smaller than that of the earth. However, the unexpectedly high value for the mass of Triton, recently found at Mt. Wilson, suggests a similar possibility for Pluto. M. Baldet, as the result of visual observations with the Meudon equatorial, concludes that the diameter does not exceed 0·2″ (Report of the Paris Observatory for 1930).

Dr. Bower's article contains an accurate ephemeris of Pluto from August 1931 to June 1932; this is for the equinox of 1900; Dr. Bower notes that this is the most convenient equinox if one uses positions of the comparison stars derived from the astrographic catalogues; these contain fainter stars than those given in other catalogues. The images of brighter stars on the Pluto plates are too large for accurate measurement.

A New System of Film Projection.

WELL-ATTENDED demonstrations were given at the premises of Messrs. Robinson, King and Co., Ltd., in Stratford, London, of an invention by Dr. R. T. A. Innes, formerly Union Astronomer, Johannesburg, for increasing plasticity and saving space in projection of films. In place of the usual screen a large plane mirror is to be installed, the picture being projected on an ordinary screen so situated that the audience sees it in the mirror. It may be behind them, or on the ceiling. In the demonstration it was behind, the projector being behind and above the mirror.

Regarding the increase in plasticity claimed, we must confess that we failed to perceive it as regards black and white films. It is also claimed that the effects of grain and scratches are masked, but the films shown were not worn; a slight diminution in the sparkle due to grain was perhaps noticeable. An excellent coloured film shown was, however, certainly improved. Colour adds plasticity to films, and Dr. Innes's plan really ‘ varnishes ’ the picture, as it were, and thus adds somewhat to the brilliance and depth of the colour. The effect is similar to the difference between matt and glazed photographs, and would finally, as in this case, be a matter of taste. The lure of devices of this kind for inventors is due to the psychological fact that any change in the tint or texture of a photograph, if it is novel, is at first pleasing, since the photograph is inherently inadequate as a representation of three-dimensional reality. The change is usually imagined to make the picture more real—to fulfil our unconscious wish: this will be remembered when the tinting of films was first introduced, and it accounts for the plastic effect of colour. The unsophisticated are immensely pleased by an extremely brilliant glaze on photographs. But these joys are fleeting: custom soon stales them.

The other advantages claimed are more substantial. Installed in a small room or hall, practically the whole floor space may be filled with seats from which a good view is obtained, since even those close to the mirror see the screen as at a convenient distance. Those at the back have a more distant view than they otherwise would, but can still see well. Thus the available space is much increased. The field for the invention is thus chiefly in small, cramped halls, and in education and advertising.

Difficulties arise from the fact that mirrors exceeding a certain size are expensive to make and handle. Even a small screen would need to be built up of two or three parts, and means would have to be found to make the join unobjectionable. Also, the film is seen reversed if projected upon the screen in the usual way, while serious loss of light occurs with through projection, apart from the fact that the gain in space would no longer be present. With on-projection, therefore, the film has to be turned round in the projector, and few projectors allow of this being done with sound-films, since it brings the sound track on the wrong side. However, one portable equipment at least is available in which this difficulty does not occur, and with such an apparatus and Dr. Innes's mirror a small room could be packed with spectators who would all get a satisfactory view.

University and Educational Intelligence.

CAMBRIDGE.—Dr. F. C. Phillips, of Corpus Christi College, has been appointed University lecturer in petrology.

In a report to the University on forestry in the University curriculum, the General Board states that there is practically no future for graduates trained in forestry except in Government forest services. Only twenty to twenty-five of these posts are available each year, and there are no fewer than five university schools, including that at Cambridge, training candidates for these posts. As a result of investigations, the Committee of the General Board concludes that the University is not justified in maintaining a forestry organisation as a recruiting ground for Government services, partly because the demand is so small, but even more because the Committee considers that University policy in forestry teaching cannot be reconciled with the present official view. It is accordingly recommended that the Department of Forestry be suppressed, examinations in forestry for the ordinary B.A. degree be discontinued after 1934, and examinations for the diploma in forestry cease in October 1935.

SHEFFIELD.—The Council of the University has made the following appointments: Mr. B. H. Bentley, lecturer in botany, to be professor of botany; Dr. R. N. Rudmose Brown, lecturer in geography, to be professor of geography; Mr. L. E. S. Eastham, to be professor of zoology; Dr. J. Florey, to be professor of pathology; and Dr. J. W. Edington, to be professor of bacteriology.

At the Indian Institute of Science, Bangalore, the service of Dr. M. O. Forster as director has been extended until April 1933. Dr. V. Subrahmanyan has been appointed professor of biochemistry.

At the end of the year Dr. R. S. Clay is resigning the principalship of the Northern Polytechnic, London, a post he has occupied for twenty-nine years. The governors, staff, students, and members of clubs and societies who have been associated with him during this long period wish to assist in offering some token of their regard and affection, and a committee has been set up to give effect to this general desire. The honorary treasurer of the committee is Mr. W. M. Macbeth, Northern Polytechnic, Holloway, London, N.7.

The International Federation of University Women has issued a report of its sixteenth council meeting, held at Wellesley College, Massachusetts, last April under the chairmanship of the president of the Federation, Prof. Winifred Cullis, and attended by women graduates of thirty-one countries. Prominent among the activities of the Federation is the establishment of research fellowships to give university women the opportunity of a year's work in a foreign country. The fund for this purpose already exceeds five thousand pounds, exclusive of the collections of the American Association of University Women, which will be allocated partly to national and partly to international fellowships.

Birthdays and Research Centres.

Dec. 20, 1876.—Dr. W. S. Adams, director of Mount Wilson Observatory.

My chief interest for many years has consisted in physical and quantitative studies of stellar spectra. Theoretical astrophysicists have carried on much able research during recent years on problems of stellar constitution and radiation, and the need for observational evidence to aid in discriminating among different theories is pressing. This is especially true of investigations dealing with temperatures and pressures in stellar atmospheres, the opacity coefficient, and the abundance of the elements in different states of excitation and ionisation.

Specific observational studies at Mount Wilson are dealing with the character, intensities, and contours of stellar spectral lines, their differential displacements, and the application of spectral criteria to the determination of the absolute brightness and the distances of stars.

Dec. 22, 1862.—Dr. Vaughan Cornish, past president of Section E (Geography) of the British Association and of the Geographical Association.

The secret of scenic beauty is the enhancement which landscape derives when the grouping happens to be harmonious, whether this be a matter of locality, as when the physical features are harmonious, or of season, as when light or colour are happily blended or contrasted.

During the last six years, I have published a number of original papers in which the principle of harmonious grouping has been applied both to the landscape of the wild and to the scenery of civilisation, and in a chapter, entitled "Watching the Seasons" in a recently published book on "The Poetic Impression of Natural Scenery" I have shown its application to the changes of sunlight and foliage.

Every advance in the systematic study of natural beauty will be a social benefit, since an enhanced appreciation of the countryside will provide the majority of our people with a corrective for the inevitable artificiality of urban life.

Societies and Academies.

London.

Royal Society, Dec. 10.—**Sir Arthur Eddington**: On the mass of the proton. From the theory of the cosmical constant developed in a previous paper, a wave equation for an electron is developed, which, however, is incomplete. The correct equation contains the factors 10 and 136, representing the number of degrees of freedom associated with the respective energy terms. The mass of a particle satisfying this wave equation is given by an equation having two roots, which evidently correspond to electrons and protons, and their ratio is 1847·60. It is verified that the two roots represent charges of opposite sign.—**P. S. H. Henry**: The specific heats of air, oxygen, and nitrogen from 20° C. to 370° C. Further developments of the new constant flow calorimeter for the determination of the specific heats of gases at constant pressure are given. These results, whilst agreeing with those obtained by the sound velocity method at room temperature, show a much higher rate of increase of the specific heats with temperature, and a closer approximation to the curves predicted by means of Boltzmann's hypothesis from the spectroscopic frequencies of vibration of the molecules.—**W. L. Francis**: Studies in membrane behaviour (1). Equilibrium membrane potentials are measured for a buffer concentration gradient of 10 : 1 using $N/40$-$N/400$ and N-$N/10$ solutions. The e.m.f.'s with and without gelatine on the membranes are compared over the pH range 2·35-7·3. The results, more particularly with weaker solutions, appear to support the modified diffusion theory, that is, the anions are retarded in basic solution and the cations in acid solution. Direct evidence, given by determinations of the transport numbers of the sodium and acetate ions across the membrane in $N/2$ solution, vetoes this theory. Assuming that the membrane potentials are made up of the ordinary diffusion potential and an opposed e.m.f. due to the combination or adsorption of ions on the protein, an explanation is suggested which conforms with the known behaviour of gelatine in electrolyte solutions.

Paris.

Academy of Sciences, Nov. 9.—**E. Jouguet**: The secular stability of the rotors of turbines. A discussion of the criteria of stability according to Stoidola's hypotheses, with the additional criterium suggested by Lamb.—**H. Vincent**: A theory of the constitution of antibodies. A comparison of the properties of antitoxins and cryptotoxins (toxin + sodium salicylate). Both form a stable complex with the toxin and both are dissociated when the pH is lowered to 4·7: although the toxin is neutralised, it is not destroyed in either case.—**André Blondel**: The mutual inductances of magnetic leaks in transformers with several secondaries.—**Erik Westzynthius**: The distribution of integers which are not divisible by any one of the n smallest prime numbers.—**A. Marchand**: Various extensions of the idea of a continuum of limited order.—**J. Favard**: A proposition of Minkowski.—**S. Finikoff**: Stratifiable parabolic congruences: transformers of R_0 surfaces.—**J. Herbrand** and **C. Chevalley**: New demonstration of the theorem of existence in the theory of the body of classes.—**H. Parodi**: The method of integration by successive arcs giving, in the calculation of the elementary arc, an approximation as close as desired.—**Georges Giraud**: Problems of values at the boundary in the case of discontinuous data.—**J. A. Lappo-Danilevski**: The construction of the normal integral matrix of a system of linear differential equations in the neighbourhood of a pole of its coefficients.—**A. Markoff**: A general property of Birkhoff's minimal ensembles.—**Jacques Devisme**: Some partial differential equations.—**Arnaud Denjoy**: A theorem of Wiman.—**Bernard Salomon**: Mechanical integrators with holonomial linkages.—**Al. Proca**: The theory of radiation.—**A. Foch** and **J. Bariol**: The motion of a viscous fluid in the neighbourhood of a disc oscillating about its axis.—**Th. Got**: The value of the Dunkerley formula and its analogues for the approximate calculation of the first critical velocity of a rotating axis.—**D. Barbier**: The distribution of the poles of the orbits of double stars.—**Maurice Curie** and **A. Lepape**: The thermal conductivity of the rare gases. A modification of the thermometric cooling method of E. Müller was used. Data are given for the first time for krypton and xenon; the previously published results for helium, neon, and argon are confirmed.—**G. Bruhat** and **J. Thouvenin**: The double refraction produced by the compression of amorphous silica and crystallised quartz and its dispersion in the ultra-violet. Two specimens of fused silica show comparable double refractions on compression, the differences between them being only 5-6 per cent. This double refraction is about 40 per cent higher than that of crystalline quartz. Havelock's formula for the variation of the double refraction with the wave-length is considered to be only a first approximation.—**Mlle. M. Quintin**: The activity coefficient of the bivalent copper ion in solutions of its sulphate. In the range of concentration studied, including some relatively high concentrations, the Debye theory applies to solutions of copper sulphate, if a correction factor for the dimensions of the ions is included.—**S. Rosenblum**: The long path α-rays emitted by $ThC + C'$ and some determinations of the velocities of the α-rays. The direct measurement of the velocity of the α-rays has been determined with the aid of the large electromagnet of the Academy of Sciences by the method of magnetic focalisation.—**Paul Woog, Mlles. Emilie Ganster** and **Fanny Coulon**: The variation of the point of thawing out of mineral oils accompanying changes in their state.—**P. Bary** and **E. Fleurent**: The degradation of india-rubber solutions of various concentrations. The changes were followed by the alterations in the viscosity of the solutions.—**L. Riéty** and **G. Salager**: An electromotive force of filtration of abnormal value. Solutions of mercuric cyanide, flowing through a capillary tube, set up abnormal electromotive forces, ranging from 0·65 to 3·025 volts with varying concentration.—**J. Sambussy**: The action of a continued difference of potential on acetone and ether.—**Maurice Lambrey**: A method of studying the decomposition of gun-cottons at the ordinary temperature. The method is based on the increase of the γ absorption bands of nitric oxide in presence of an inert gas (hydrogen). Clear evidence has been obtained by this method that various specimens of carefully purified gun-cotton evolve traces of nitric oxide at 30° C.—**André Kling** and **Daniel Florentin**: The mode of action of dehydrating catalysts in the hydrogenating cracking of phenols. Contrary to expectations, the activity of certain catalysts (alumina, blue oxide of molybdenum) is increased by a preliminary heating to 750° C.—**Frèrejacque**: The autoxidation of uric acid in the presence of amines.—**E. Aubert de La Rüe**: The extension of the granular eruptive rocks in the Kerguelen Archipelago.—**Yang Kieh**: The prolongation towards the west of the dislocated zone situated to the north of the Marche chain.—**Henri Besaire**: The stratigraphy of the sedimentary formations of the province of Analalava, north-west Madagascar.—**V. Frolow**: The fall of the Oronto in 1929–30.—**E. Diénert**: The condensation of water vapour in the soil.—**Mlle. Lucie Ricard**: The vascular insertion of rootlets.—**A. Kopp** and **D. d'Emmerez de Charmoy**: New results on the diseases of sugar cane and maize.—**Polack**: Which colours do all colour-blind people fail to distinguish? A modified test for colour-blindness is suggested, stress being laid on the separation of blue, violet, purple, and greenish blue. Separation of the red and green is possible in certain colour-blind people.—**Raymond-Hamet**: The indirect vaso-dilatory action of the ergot alkaloids.—**Fernand Mercier**: The influence of dextrorotatory pseudo-cocaine on the hypertensive action of adrenaline. The two optically isomeric cocaines have a different physiological action as regards the hypertensive effect produced by adrenaline.—**Mme. M. L. Le Roux**: The experimental removal of the ovaries of *Gammarus* and its effect on the evolution of the oostegites.—**A. Vandel**: The existence of males of parthenogenetic origin and the genotypical constitution of the parthenogenetic females of *Trichoniscus* (*Spiloniscus*) *Elisabethæ*.—**J. Parrod** and **Mlle. Y. Garreau**: The oxidation products of *d*-mannose by ammoniacal copper oxide in the presence of air, at the ordinary temperature. The oxidation products, oxalic acid, imidazol, and *d*-arabino-tetroxy-butyl-4-imidazol, were the same as those previously isolated from the oxidation of *d*-glucose under similar conditions.—**H. Belval**: The lævorotatory glucides of the bulbs of *Lycoris*.—**F. Vlès, A. de Coulon**, and **A. Ugo**: The factors of the evolution of tar cancer in mice.

ROME.

Royal National Academy of the Lincei, May 17.—**T. Levi-Civita**: Concerning the notes of Hatzidakis and Sakellariou on central motions.—**C. Miranda**: Extension of the theorems of Hilbert-Schmidt and Picard to singular linear integral equations.—**C. Rimini**: The flexion of surfaces.—**T. Viola**: Noteworthy properties of continuous functions.—**Pia Nalli**: Rigid transports of vectors on surfaces. The results previously deduced for varieties with any number of dimensions are applied to surfaces.—**W. Fenchel**: Channel waves of permanent type.—**N. Hatzidakis**: Observations on a paper by M. Sakellariou on "A Class of Central Motions".—**A. Belluigi**: The gravimetric depression of Carpaneto.—**M. Lombardini**: Geometric considerations for periodal analysis. The properties of the extremes, zeros, and flexes of the sum of two sine curves, previously considered, are now utilised for deducing the necessary simple conditions to be satisfied by the distribution of the zeros, extremes, and flexes in order that a curve may be regarded as the sum of two sine curves.—**Orazio Specchia**: Raman spectrum of the ion SO_4.—**R. Zoja**: The distribution of the tensions in a solid with rectilinear axis and with rectangular transverse section of variable dimensions (3).—**R. Einaudi**: The relations existing between Euler's variational equations and the canonical equations of mechanics.—**Goffredo Vitali**: The calculation of a lens. Pacella's method of calculating a plano-convex lens leads to very simple results when the plane face is replaced by a spherical surface with its centre at the focus of the lens.—**Paolo Straneo**: The unitary theory of gravitation and electricity (3). Further consequences of the unitary equations. Certain considerations, mainly qualitative, bearing on the author's unitary theory are discussed, with some of the more immediate and simpler consequences, and the general scope of the theory.—**L. Malossi**: Double sulphates of bismuth with alkali metals (2). Double sulphates of bismuth and lithium. The system $Bi_2(SO_4)_3$-Li_2SO_4-H_2O forms the two compounds, $Li_3Bi(SO_4)_3, 2H_2O$ and $Li(BiO)SO_4, H_2O$.—**P. Pratesi**: Reactions of addition to unsaturated organic compounds. Application of the electronic theory of valency to unsaturated molecules of various types results in verification of all the regularities with regard to the formation of additive compounds established by Markownikow and Ipatiew for particular classes of compounds.—G. B. Bonino and P. Cella: Raman spectrum of hydrogenated derivatives of naphthalene. The Raman spectra of deca- and tetra-hydronaphthalene are compared with those of naphthalene and cyclohexane.—G. B. Bonino and L. Brull: Raman spectrum of dichlorobromomethane. Whereas the Raman spectra of chloroform and bromoform exhibit six frequencies, five of them intense, dichlorobromomethane displays one more, owing to the possibility of oscillations Cl-Br, this not occurring with the other two compounds. The ratio between the values of $\cos^2\beta$ for chloroform and bromoform equals the inverse ratio between the permanent electric moments for the two compounds. If this relationship holds also for dichlorobromomethane, the electric moment for this compound should be $1{\cdot}25 \times 10^{-18}$.

Diary of Societies.

FRIDAY, DECEMBER 18.

SOCIETY FOR EXPERIMENTAL BIOLOGY (in Department of Zoology, University College), at 10.30 A.M., at 2.15, at 4, and at 5.30.

ROYAL SOCIETY OF MEDICINE (Physical Medicine Section), at 5.30.—Prof. A. V. Hill: The Liberation of Energy by Muscle (Samuel Hyde Memorial Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.

SOCIETY OF DYERS AND COLOURISTS (Glasgow Section) (at George Hotel, Glasgow), at 7.15.

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at Royal Technical College, Glasgow), at 7.30.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College, Cardiff), at 7.30.—Christmas Lecture.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (jointly with Leicester Association of Engineers) (at College of Technology, Leicester), at 7.30.

SOUTH LONDON BOTANICAL INSTITUTE (at 323 Norwood Road, S.E.24), at 8.

INSTITUTE OF CHEMISTRY, at 8.—Sir Frank E. Smith: The Chemist and the Community (S. M. Gluckstein Memorial Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Rev. Dr. C. Alington: The Education of the Average Man.

SATURDAY, DECEMBER 19.

SOCIETY FOR EXPERIMENTAL BIOLOGY (in Department of Physiology, University College), at 10.30 A.M., and at 2.15.

BRITISH PSYCHOLOGICAL SOCIETY (Annual General Meeting) (at 55 Russell Square, W.C.1), at 2.30.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Roger Fry: Great French Painters (3).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees-Side Branch—Graduate Section) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.

MONDAY, DECEMBER 21.

ROYAL GEOGRAPHICAL SOCIETY, at 5.30.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with South Wales Section of Institute of Chemistry) (at Cardiff Technical College), at 7.30.—Christmas Lecture.

TUESDAY, DECEMBER 22.

LONDON NATURAL HISTORY SOCIETY (at London School of Hygiene and Tropical Medicine) (Plant Galls Section), at 6.30.

INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Centre) (at Segrave Club, Wolverhampton), at 7.30.

Discussion.

TUESDAY, DECEMBER 22.

CONWAY HALL (Red Lion Square), at 7.—Dr. F. H. Hayward and the Celebration Fellowship: Celebration of Science (Geology).

Official Publications Received.

BRITISH.

Report of British Delegates of the Meeting of the International Council for the Exploration of the Sea, held at Copenhagen, March 23rd-28th, 1931. Pp. 9. (London: Ministry of Agriculture and Fisheries.)

India: Meteorological Department: Scientific Notes. Vol. 3, No. 30: The Structure of the Sea-Breeze at Poona. By Dr. K. R. Ramanathan. Pp. 131-134+9 plates. 1 rupee; 1*s.* 9*d.* Vol. 4, No. 31: The Lunar Atmospheric Tide at Kodaikanal and Periyakulam. By Dr. S. K. Pramanik, S. C. Chatterjee and P. P. Joshi. Pp. 5. 4 annas; 5*d.* (Calcutta: Government of India Central Publication Branch.)

The Parliament of the Commonwealth of Australia. Report on Tour of Inspection of the Oil-Fields of the United States of America and Argentina, and on Oil Prospects in Australia. By Dr. W. G. Woolnough. Pp. 118. (Canberra: H. J. Green.) 5*s.*

Mysore Geological Department. Records, Vol. 29, 1930. Pp. iv+38+2 plates. (Bangalore: Government Press.) 2 rupees.

The North Staffordshire Field Club. Transactions and Annual Report, 1930-31. Edited by the Rev. E. Deacon. (Vol. 65.) Pp. 169+A25-A50+7 plates. (Stoke-on-Trent.) 7*s.* 6*d.*

The Indian Forest Records. Vol. 15, Part 3: Standard, Commercial and Heartwood Volume Tables (Factory Working) for Khair (*Acacia catechu*, Willd.) in North India. By H. G. Champion and Ishwar Das Mahendru. Pp. iii+16. 5 annas: 6*d.* Vol. 16, Part 5: Investigations on the Seed and Seedlings of *Shorea robusta* Gaertn. F. By H. G. Champion and B. D. Pant. Pp. v+33+6 plates. 1.6 rupees; 2*s.* 3*d.* (Calcutta: Government of India Central Publication Branch.)

Journal of the Chemical Society. October. Pp. v+2509-2831+x. (London.)

The Zoological Survey of India. Memorandum on the Proposals for Retrenchment. By Sir C. V. Raman. Pp. 19. (Calcutta: The Author, 92 Upper Circular Road.)

Biological Reviews and Biological Proceedings of the Cambridge Philosophical Society. Edited by H. Munro Fox. Vol. 6, No. 4, October. Pp. 345-482. (Cambridge: At the University Press.) 12*s.* 6*d.* net.

Proceedings of the Royal Society. Series A, Vol. 134, No. A823, November 3. Pp. 356. (London: Harrison and Sons, Ltd.) 18*s.*

Canada: Department of Mines. Mines Branch. Investigations in Ceramics and Road Materials (Testing and Research Laboratories) 1928-1929. (No. 722.) Pp. ii+143+3 plates. (Ottawa: F. A. Acland.)

Department of Agriculture: New South Wales. Veterinary Research Report No. 6, Parts 1 and 2. By Dr. H. R. Seddon. Pp. 91+6 plates. (Sydney, N.S.W.: Alfred James Kent.)

Bulletin of the Department of Zoology, Panjab University. Vol. 1: Fauna of Lahore. 2: Entomostraca (Water-Fleas) of Lahore. By G. L. Arora. Pp. 62-100+plates 5-8. (Lahore.) 3 rupees.

British Cast Iron Research Association. Tenth Annual Report for the Year ending June 30th, 1931. Pp. 16. (Birmingham.)

National Needs (II.).

> “Son, I am wearied of that Madrissah (school) where they take the best years of a man to teach him what he can only learn upon the road.”—*The Mahbub to Kim.*
>
> “*Sciencia vinces*—whether it be on the field of battle, on the waves of the ocean, amid the din and smoke of the workshop or on the broad acres under the light of heaven ; assuredly, in the future, even more than in the past, not only the prosperity but even the existence of the Empire will be found to depend upon the ‘improvement of Natural Knowledge’—that is upon the more complete application of scientific knowledge and methods to every department of industrial and national activity.”—*Sir Wm. Huggins* (1905).

WHAT, precisely, are we to do ? Mr. Louis Anderson Fenn asks (NATURE, Nov. 28, p. 909) in commenting upon my article on “National Needs”. He summarises my contentions in saying, that due appreciation of the *method of science* should be part of the cultural equipment of the citizen, adding : this can only be brought about through *a new kind of scientific education*, differing from the current type in having a definite social and political reference. I agree—but it is a little late to ask me to create and sustain such a movement. My article was a trumpet-call to this end ; my whole life, since 1870, has been consciously devoted to such purpose, I am obliged to confess, with little constructive success, except that I have learnt how all but insuperable are the difficulties to be overcome ; how every advance that we would make is subject to reduction by an overwhelming indeterminate factor—human nature.

The fundamental difficulty is to secure agreement as to the meaning of the label *scientific.* A science is a body of knowledge ; to be scientific is something very different from having knowledge : it means knowing how to make complete use of knowledge. The pioneer workers, in whatever field, are necessarily scientific ; yet among these, only a small minority are consciously scientific ; very few know how priceless a gift they have in their possession or seek to use it outside their specific work ; the majority act intuitively. I well know how long it was before I was clearly conscious of a guiding purpose behind my own efforts. The fact is, as I have often said, original inquiry is artistry pure and simple and the artist, we know, is rare. Artists are not noted for their common sense. Even in the narrow field of experimental inquiry, we have still to learn to exercise *proportionate judgement*, for which see Faraday's lecture on “Mental Education”, delivered before

Prince Albert in 1854. The doctrine Faraday professed should be our profession of faith: read frequently, as a lesson, in every church and in every school, in every laboratory before beginning work—if it be in us to rise so high and to have and hold a scientific faith. I agree with Mr. Fenn that our present-day 'science' is as ambiguous as the Christian faith. I would say not only politically but in all respects.

The Bishop of Birmingham said recently "that on this earth life would flicker out when the solar heat passed away but, in some other realms, he was forced to assume all that was of value in his personality would endure". Even mitred heads can asseverate, "I know it's true but I won't believe it". Why assume anything of an inconceivable situation? Our textbooks are full of similar proof of the prevalence of dogma. This is our difficulty—we do not hold to the truth even in teaching so-called science. In short, we have to cure ourselves before operating upon the public confidence. Few, probably, are educable to a scientific faith; most of us are inescapably credulous. Yet I believe much might be done with the multitude, if only a few of us could rise to the height of the opportunity before the teacher; could see how great is the peril in which we now stand and the call for the supreme effort calculated to raise our mental and moral standards; could combine in such crusade.

There must be a focus point. There is but one: the *Royal Society*. No collegiate body is likely to undertake the task—the literary mind being definitely incapable of understanding and using the experimental method. At the head of this article I have quoted words used full five and twenty years ago by the president of the Society, the late Sir William Huggins, a man to be ranked with Faraday as a lover of truth and a master of philosophical method. In justification of the claim he made, he added the statement:

> "It is obvious that it must be so, for it is only through an increased understanding of what are called the laws of Nature—the sequence and the interaction of natural phenomena—that we can hope to bring Nature into complete subjection and to make use of her illimitable forces to work out our own ends."

In the interval, the growth of 'natural knowledge' has been marvellous. Unfortunately, the control man has secured over Nature in no way extends to himself. We are faced with the fact that he is incapable of managing his ordinary affairs. Chaos now prevails throughout the world: we seem to be unable to do more than await events; we have no considered policy; no men competent to evolve one in any considered way. The astounding revelation has come upon us that the commercial community has no method of business—the banking fraternity, perhaps least of any, in view of the magnitude of its business and the trust imposed in it by the public. We have lived, it seems, upon the 'confidence trick': confidence being lost, the game cannot go on. The world is like Hans Andersen's 'King that had no clothes': at the mercy of pretending weavers. Money-making, as the aim and end of life, the American religion, is being made impossible by over-running the machinery which has made such doctrine possible. This is why I say that "a wise socialism is foreshadowed". Man is necessarily and by nature selfish but scientific advance will only be possible if he learn to subordinate his individual desires and be rational. This is our difficulty—to overcome our human nature.

To quote Sir William Huggins:

> "Clearly, it is only by such a widening of the general education common to all who go up to the Universities, before specialisation is allowed, that the present 'gap between scientific students of literary form, and classical students ignorant of scientific method' can be filled up, and the young men who will in the future take an active part in public affairs, as statesmen and leaders of thought, can be suitably prepared to introduce and encourage in the country that fuller knowledge and appreciation of science which are needed for the complete change of the national attitude on all science [scientific] questions, which is absolutely necessary if we are to maintain our high position and fulfil our destiny as a great nation."

The Society had memorialised the universities in the previous year (1904), begging them to take steps to ensure that *a knowledge of science* should be recognised in schools and elsewhere as an essential part of general education. The schools and universities may answer that this has been done. Those of us who are alive to facts, however, know that the object aimed at by Sir William Huggins has in no way been accomplished. Examinations have more and more prevailed to prevent the desired change; now even the teachers hug the chains that have been hung around them. Thereby hang coaching fees, examiners' fees, bold advertisement of schools and fond parents' worship of Tommy and Jane's successes. All very human—but bad business. A certain number of expert scientific workers has been brought into being under the system but the public mind, the business mind, the administrative mind, is untouched, in no way *disciplined* to grasp the complexities of our modern life.

Sir William Huggins—I knew him intimately—knew well what he wanted: a more complete application of *scientific knowledge and method* to every department of national and industrial activity. He had no desire that the stars should be understood: yet every desire that the method which had enabled him to understand them should be clear to all—the experimental method, the method of exercising sound scientific thought—thought replete with knowledge and action based upon such thought.

The Royal Society has done nothing, during the twenty-five years' interval, to carry out its former president's behest and support its own action. We are more and more developing bureaucratic habits and academic impotence, making natural science a close corporation; worse still, an inordinate vanity is growing upon us, through excessive publication and prize-giving. No other class, let us confess, gets itself so much talked about and rewarded for so little real service. Courage of opinion is gone; there is no evidence among us of any clear sense of responsibility, let alone of patriotism. Yet in our hands rests a terrific power, if we would but use it—as there must ever be in real knowledge. Present-day engineering achievement, patent to the public on every side, the outcome of considered thought and exact work, is sufficient evidence not merely of what is but of what might be, if we combined our forces to useful public ends. The engineer is not actuated solely by thought of gain; a greater end, the glory of achievement, counts for much. The late Sir Charles Parsons's concern was to make the turbine a perfect machine; whether it paid was a secondary consideration—far more his friends' consideration than his own.

Man is a far finer machine than any turbine or, indeed, any engineering achievement—yet we give no real thought to his improvement. We seek to administer remedies when he falls into ill-health but do little, if anything, to render him proof against disease. In seeking to gain mastery over Nature, we neglect our own souls. The schools for our young gentlemen are in the hands of most respectable governing bodies who unconcernedly continue to support the grand old fortifying, classical curriculum, with its religious accompaniments; they rarely elect a 'head' who is not its advocate. Not a single school stands out as engaged in the conscious and calculated practice of real scientific method. The condition of our schools is heart-rending to some of us who know—considering what they might be. It is true—Rome was not built in a day; still, I have watched school building operations during sixty-five years and can record little progress. Lytton Strachey tells us that Dr. Arnold elected not to teach physical science at Rugby (1828):

> "Obviously only two alternatives were possible, it must either take the chief place in the curriculum or it must be left out altogether. Before such a choice, Dr. Arnold did not hesitate for a moment. 'Rather than have physical science the principal thing in my son's mind,' he exclaimed in a letter to a friend, 'I would gladly have him think that the sun went round the earth and that the stars were so many spangles set in the bright blue firmament. Surely the one thing needful for a Christian and an Englishman to study is Christian and moral and political philosophy.' "

Even to-day, men of my school make no demand for physical science. We ask only that the underlying method, which has made modern, post-Arnoldian progress possible, be taught with interest and full honesty of purpose; as a philosophy but through practice and with reference to life. In my own case, interest was first awakened through the study of words—and the sight of butterflies—not through 'stinks'; but possession came only through engaging in experimental inquiry.

Organise our scientific forces we must. The Royal Society alone can take the lead. It should forthwith constitute its fellows a parliament of scientific opinion, sub-dividing it into sections, according to subjects, if desirable; also co-opting a limited number of specially competent persons from outside the Society. Our first act would be to learn to take counsel together for the common good—a hitherto unknown art unpractised by scientific workers: this would be the prelude to the establishment of a limited scientific democracy, the beginning of my scientific socialism.

Constantly complaint is made that scientific workers are not used by Government or in the public services. Why should we be, when we do not set the example of using ourselves? "Physician, heal thyself", after all, is an expression of worldly wisdom; "Charity begins at home" is another. It rests with the Society to show openly that there is an intellectual method behind all its activities and, by example, to encourage the development of the scientific temper of mind in the community. Need I say more by way of giving the lead that is asked of me? Personally I pursue one hope:

"To the solid ground of Nature trusts the mind that builds for aye." H. E. A.

Science and Philosophy of Life.

Life: Outlines of General Biology. By Sir J. Arthur Thomson and Prof. Patrick Geddes. Vol. 1. Pp. xix + 714. Vol. 2. Pp. xi + 715-1515. (London: Williams and Norgate, Ltd., 1931.) 63*s*. net.

WHEN two men of science, with the ripe experience of Sir J. Arthur Thomson and Prof. Patrick Geddes, combine to give the world their finished thoughts about life, the result is likely to be unusual and instructive. These volumes are both. They contain no ordinary exposition of general biology, for, instead of the formal treatment of themes which incline to become stereotyped, they embrace less ceremonious discussions of the facts generally classed as biological, and pass beyond these, aided and abetted by the authors' long intimacy with teaching and with civic endeavour. So that their net, wide-mouthed and fine-meshed, seems to catch almost everything that floats in the ocean of life.

The treatment of the themes in general cannot fail to remind one of the works of the older naturalists, where anecdotes formed the supporting skeleton upon which the body of generalities was built; only here the uncritical anecdotes of the early field naturalist are replaced by authenticated observations and by records of experiments drawn from a wide knowledge of recent biological investigation. The method has this great advantage for the general reader, that at almost any page he may dip into these two great volumes and find himself interested in an example or a theme, carefully labelled and complete in itself, but in reality an item in a massed argument for some particular generality. For the student or the teacher of biological subjects the advantage of the method lies in the wealth of facts which have been marshalled here for his conviction, to give body to the argument, and which secondarily form a gold-mine of information from which he may extract nuggets at his leisure.

Another impression made by the design of the work is that the authors are conscious, as every follower of the science must be, of the unwieldy masses of evidence which have accumulated, and that by a *tour de force* they have compelled the multifarious evidences, differing in quality and degree, to fall into line and play a part in support of their biological theses.

A fourfold purpose animates the book. Its first aim is to state and illustrate the outlines of biology as generally understood—the characteristics of organisms, their ways of acting in relation to their own organisation and in relation to their inanimate and animate environment, their development as living units, and their evolution as items in the complete tale of life's progress. Characteristic of this great section (of more than 900 pages) is the successful endeavour to import into the discussions a real flavour of livingness and of the wonder and drama of life. A second purpose is focused upon an examination of the science of biology, first as to its constituent branches, and second as to its place in the field of knowledge, its relation to the sciences and the arts; and here we are faced with subtle schemes of inter-relationships, as intricate as the web of life itself, which culminate in the mystical end papers of the volumes and their necessary but illuminating interpretation.

In the third place, throughout the whole work, which is marked by a philosophic synthesis of the factual groundwork, there runs the continuous thread of the neo-vitalistic outlook; but the treatment is cautious, and full weight is given to the discoveries of the biochemist and biophysicist, though insistence is made upon the need still for concepts characteristic of and peculiar to the life sciences.

Finally, the authors very properly bring together again for the consideration of their fellow-workers the special contributions to biological interpretations which their earlier writings have made familiar—the metabolic theory of sex, the inclined plane of animal behaviour, the concept of the cell-cycle with its morphological and physiological counterparts, the restatement of the concepts of reversion and parasitism, and so on.

No part of the "large and crowded volumes", however, so reveals the reactions of these skilled teachers to their long experience of education and of life as the final chapters and appendices. There, in discussing man and the wider aspects of biology, they let themselves go, and from a series of talks about many things they reach forward to a theory of life, "evolutionary throughout, from organisms at simplest to humanity at highest", in which due place is found "for each and all the contributory sciences, for the occupations and the arts, and for literatures and philosophies as well". Since the biological outlook lies at the foundation of this evolutionary integration, a strong plea is made for the further teaching in school and college of biology, "the general science of organisms—the study of the nature, persistence, continuance, development, and evolution of life". Of first-class zoology and first-class botany there is abundance, but "our frank reproach is that the Universities, within and beyond the British Empire, fall short of their just ambition as regards Biological Education". The cultural course for 'arts' students might well be oriented, on a sound basis of correlated structure and function, towards the old-fashioned natural history, which would stimulate dormant interest and fill the mind with concepts later to be applied subconsciously and automatically in any walk of life. As a basis for medical studies, what could be more telling than the driving home, by practical exercises and observations, of the great biological concepts of growth, development, correlation, variability, heredity, evolution, and so forth, with excursions, where need be, into issues of special significance to medicine? It is a strong plea for 'biology for life'.

In places this is a wayward work, occasionally discursive and diffuse, occasionally unnecessarily repetitive, mostly clear and easy in style, sometimes tantalisingly involved, but it has an atmosphere of its own, which, with its wealth of facts and its ideals, will well serve its purpose of furthering an interest in the science of life and in life itself.

James Ritchie.

Second Thoughts on Radiotelegraphy.

(1) *Modern Radio Communication: a Manual of Modern Theory and Practice, covering the Syllabus of the City and Guilds Examination and suitable for Candidates for the P.M.G. Certificate.* By J. H. Reyner. Third edition. Pp. xi + 259. (London: Sir Isaac Pitman and Sons, Ltd., 1931.) 5*s.* net.

(2) *The Cable and Wireless Communications of the World: a Survey of Present Day Means of International Communication by Cable and Wireless; containing Chapters on Cable and Wireless Finance.* By F. J. Brown. Second edition, revised. Pp. xi + 153. (London: Sir Isaac Pitman and Sons, Ltd., 1930.) 7*s.* 6*d.* net.

(3) *The Theory and Practice of Radio Frequency Measurements: a Handbook for the Laboratory and a Textbook for Advanced Students.* By E. B. Moullin. Second edition, entirely re-set and greatly enlarged. Pp. xii + 487. (London: Charles Griffin and Co., Ltd., 1931.) 34*s.* net.

THE new edition of a technical work presents acute problems to the author, the publisher, the librarian, the reader, the editor, and the reviewer. A rapidly advancing art and a widely distributed literature demand frequent revisions of these 'zusammenfassenden Berichte' on which the harassed worker must increasingly depend. But the author and his publisher must find it difficult to determine the appropriate moment at which to revise, and the conditions in which revision should be embodied in a new work rather than in a new edition. The librarian and the reader have to face the problems of expending money in purchasing and time in reading the revised or enlarged works; on the editor and reviewer devolves the special responsibility for guiding them on the degree of novelty or value embodied in the new edition, without dereliction of their primary duties towards entirely new works.

(1) Mr. Reyner's book, first published in 1923, is designed "to cover the City and Guilds examination in the subject". It is of the essence of a plan thus restricted that there should be some superficiality of treatment, and a judicious superficiality is not a defect. But there is evidence that the revision work of the 1925 and 1931 editions has not been sufficiently thorough, with the result that in places the allocation of space is disproportionate, in others the treatment is actually erroneous. If, indeed, a completely fresh work is not here called for, pruning of the sections on obsolescent apparatus like the arc transmitter, the high-frequency alternator, and the frequency changer, expansion of the apparently hasty additions dealing with screen-grid valves, and a complete re-writing of the sections on atmospherics and on the Heaviside layer, neither of which represents the position even of 1928, may be recommended.

(2) Mr. Brown's book was, in its original form, unique as a guide to the difficult economic technical and administrative problems of world communications by cable and by wireless. His rare combination of experience in State and private enterprise admirably fits him for his task, and the fresh information embodied in the present volume is characteristic of the appropriate treatment of new editions. The book may be unhesitatingly recommended to all who are interested in the vital problems of close linking of the Empire and the world by electrical communications.

(3) Mr. Moullin's "Handbook for the Laboratory and a Textbook for Advanced Students" attained a deservedly high reputation in its first edition of some 270 pages. That the preface to the first edition was written from the Engineering Laboratory, Cambridge, while that to the second edition comes from a corresponding address in Oxford, is perhaps not the least significant change in this story of radio frequency measurements, which now occupies nearly double the space to which it was formerly confined. Even though it

belongs to the first edition, a cautionary statement in the 'Cambridge' preface is of such importance to the worker from other fields on his entry into radio-frequency measurement that we quote it without apology:

> "In high-frequency work we are again and again forced to remember that inductance, capacity and resistance are attributes possessed simultaneously by all apparatus, and we cannot say this is an inductance or that a capacity with the easy non-chalance of the power engineer. Therefore the chapter headings in this book are bound to be a little fictitious."

The greatest innovation in the new edition is the introduction of a new chapter (i.), "Developing the Electromagnetic Equations and Calculating the Field near Circuits and Aerials". "This chapter forms a focus for the book, but is not meant to be a full exposition of the equations of the electromagnetic field." So long as this limitation is fully recognised, the heroic effort of compression into forty pages may be commended, but the chapter is certainly not in itself a sufficient introduction to the equations; it should be used only for re-proportioning knowledge acquired from other sources.

For an account of the main plan of the work the reader must be referred to the review of the first edition (NATURE, Jan. 29, 1927, p. 155). The chapter which has attained the greatest expansion is that on the valve generator, now nearly three times its former length. The treatment is satisfactory within the limits adopted, but the crucial question of frequency stability is too lightly dismissed, and might well be given more weight in the next edition. The problem of the acoustic-frequency generator also merits fuller handling; in particular, the diagram for a beat-frequency generator might readily have been made very much more useful by the addition of a schedule of circuital element values, since it represents a generator which is only "very perfect" if certain stringent but sufficiently familiar conditions, not detailed in the text, are satisfied.

The chapters on measurement of potential difference and current, and on measurement of capacity, deal with fields in which the author has himself made especially valuable contributions, and contain discussions of the thermionic voltmeter, the dynamometer ammeter, and the tubular variable condenser, the two latter instruments having been devised by him since the publication of the first edition. There is now available a not inconsiderable literature of thermionic voltmeters, in which the departures from the author's original patterns are of great practical significance; fuller reference to these contributions would have been useful. The dynamometer ammeter and the Moullin condenser are instruments of great elegance and importance; it is very satisfactory to have an adequate discussion of them in the handbook.

The chapter on the intensity of radiated fields has been very little expanded, and it must be confessed that this is symptomatic of the not entirely healthy state of the subject. It may be hoped that the recent decision of the International Union for Scientific Radiotelegraphy to undertake a comparative study of the methods of field measurement will lead to the resolution of present doubts and difficulties.

One of the most surprising features of the book is that it contains no description or illustration of the normal equipment of the radio laboratory. The sub-standard wavemeter, the standard signal generator, the attenuation box, the Campbell capacitance bridge are in hourly use in the technical laboratory, but they would come almost as novelties to the reader of this work. The range and flexibility of the filter circuits of everyday practice are, too, much in excess of anything that might be inferred from the four pages which the author devotes to them. It may be added that a section on filter circuits which does not refer to Campbell, Zobel, Johnson, or Shea is an unexpected phenomenon. There are, perhaps, other evidences of insularity in the name index, but even this does not explain the absence of a reference to Bartlett on filters.

On the merely editorial side it may be suggested that the footnote which economises for the publisher by the use of "loc. cit." and "id.", where multiple references to many works of a few authors are in question, makes extravagant demands on the patience and perspicuity of the reader, who merits the greater consideration.

These notes are critical, and that they have been set down in detail must be taken as a token of the high regard in which the book as a whole is held. It is alone of its kind, it is extremely good, it should be in every high-frequency laboratory, and possession of the first edition does not excuse failure to acquire the second. But we venture to suggest that while the second edition is probably as good as any one author can make it, Mr. Moullin would increase the already heavy debt we owe him if, in proceeding to a third edition, or to an equivalent new work, he would take to himself one or more collaborators in the herculean task of preparing the ideal and monumental "Handbook of Radio Frequency Measurements".

Forest Travel in the Tropics.

Tropical Forests of the Caribbean. By Tom Gill. (Published by the Tropical Plant Research Foundation in co-operation with the Charles Lathrop Pack Forestry Trust.) Pp. xix + 318 + 81 plates. (Yonkers, N.Y.: Tropical Plant Research Foundation, 1931.)

THE Spaniard Cortez is known as a brave man, with an indomitable spirit and an almost inhuman quality of endurance. The American Tom Gill, more than four hundred years later, in adventuring the survey of the tropical forests of the Caribbean, required a very different kind of courage, and found a very different world, which was traversed in a very different manner. After reading Mr. Gill's book, the reader will reflect upon what the condition may be when another four hundred years have passed, but at present Mr. Gill, in association with the Charles Lathrop Pack Forestry Trust, has presented us with an interesting and informative up-to-date account of these forests.

Cortez, and those other bold adventurers who followed him in rapid succession, spoke of the marvellous forests of rare and unknown timbers. Mr. Gill says: "Cuba, seen through the eyes of Columbus, was a place of lovely verdure to be described only by the most glowing words in his vocabulary. It was a place of cool and fragrant woodlands, made up of trees of strange varieties, displaying leaves, flowers, and fruits of kinds he had never seen", and he refers to "the infinite number of fine, large, green trees", and "the verdure of the place, tempted me to fix there for ever". He also quotes Henry Hawks, writing in 1572, who said: "There are marvellous great woods, and as faire trees as may be seene of divers sorts, and especially firre trees that may mast any shippe that goeth upon the sea".

From the opening pages throughout to the end there is a mournful story of the way in which successive generations visiting the Caribbean have destroyed these forests. It seems as though the march of civilisation has proclaimed everywhere the destruction of trees over the wide surface of the globe.

The book is divided into sixteen chapters, among the titles of which are "Effects of Human Occupancy", "British Forestry in Tropical America", and "Tropical Forests and To-morrow", with others divided into the different countries—Porto Rico and Haiti; Central America and the West Indies; Mexico; Venezuela and Colombia—giving full information regarding each country; and it is enlivened by no less than eighty excellent pictures taken on the spot.

With the text supplemented by the pictures, the reader is enabled to visualise the existing conditions; the forester to gain necessary information; and all of us to learn a lesson to-day to plant beforehand, and so to lay up for those who follow us a rich heritage in the place of a vast deforested country.

No light feat of hardihood and endurance was required to accomplish this work, necessitating three winter visits—two by Mr. Gill and one by Mr. Barbour, Mr. Gill paying a special tribute to the value of aeroplane survey.

The writer combines the qualities of the scientific worker with the mature knowledge of a lumberman, so that the fortunate blending of both points of view increases the value of his catalogued information. It is consoling for us to read:

> "one has to confess that British forestry has gone further in the American tropics than United States forestry", and for the American an alarming note when he says, "Nor does there seem to have been at any time, including *the present*, a real adequate effort on the part of Government and individuals to place the United States on a self-supporting timber basis. The American lumberman has cut his way across the Continent; and now is hacking out the *last great* stand of virgin timber within the Continental United States, the Douglas Fir region of the Pacific North-West."

There is an arresting thought expressed in the following words:

> "Throughout the world there is a very fundamental relationship between man and trees, and in the tropics one sees it on every hand—a delicately balanced relationship, dangerous to destroy."

This pronouncement is illustrated and emphasised by the pictures of the deforested hill-top in Haiti in contrast to the year-old plantation in Trinidad and the mahogany forest in British Honduras, and other pictures. The author continually refers to, and stresses, the destructive effect on the climate and health of the people as the result of deforestation. He specially refers to the altered climate in the valley of Mexico. He says:

> "Not more than twenty-five years ago it was extremely rare that high winds would raise even small clouds of dust over the City of Mexico. To-day from December to April the wind blows with great force, bearing large quantities of fine dust that hover like clouds over the city and settle there. . . . All these conditions conspired to convert regions once forest-covered into desert, and created a serious menace through soil erosion. More than one Mexican forester has pointed out that the effect of forest destruction on climate, soil, and water flow

has brought about the abandonment of many flourishing towns.

"In old documents are still preserved requests for permission to cut trees necessary to be removed in grading for new cities and making highways in regions which to-day are desert and desolate of all trees. One finds, for example, permission granted many years ago to cut oak and pine about Saltillo, showing that in those days the region was at least partially covered with some kind of forest vegetation. To-day it is desolate." The author then pays a special tribute to Miguel A. de Quevedo, whom he calls the "Father of Mexican Forestry".

Appended to the book is a list of the better known broad-leaved species of the Caribbean region.

There is perhaps too much repetition and occasionally an absence of information which the expert in fine woods would have valued, but on the whole the book adds greatly to the world's knowledge of this wonderful tract of forest country, which includes a considerable area of yet unexplored forests, and provides a lesson to the whole world on the urgent importance of vigorous reafforestation based on scientific principles.

Short Reviews.

Maize in South Africa. By A. R. Saunders. (South African Agricultural Series, Vol. 7.) Pp. 284 + 72 plates. (Johannesburg: Central News Agency, Ltd., 1930.) 20*s.* net.

THIS book will naturally be of most interest to those vitally concerned with the cultivation and disposal of maize in South Africa, but students of the problems which arise when an economic crop undergoes rapid development in a new region will also find it of value.

Maize viewed as a world crop occupies first place in respect of tonnage. Of the 131 million tons produced, the Union of South Africa is responsible for about 2½ million, so that it is as yet one of the minor producing countries. None the less, 40 per cent of the cultivated land of the Union is occupied by maize, and nearly four-fifths of the crop is exported. Compared with other countries, the yield of maize in the Union is low, being less than one-half of that of the United States, and the future of the industry rests more on the possibility of increasing the yield per acre than in the extension of the existing area. In this, the position has some similarity to that of sugar beet cultivation in England.

The author discusses in detail the factors affecting the yield of maize in South Africa. Climate, soils, fertiliser treatment, and systems of cultivation are all dealt with in an interesting way. As in many relatively undeveloped countries, superphosphate plays a great part in crop production and is by far the most important fertiliser in the maize-growing areas, where it gives quite striking results. A further factor in improving yield is inter-cultivation with the object of checking weeds, and some interesting experimental data are given on this point. The most direct method of crop improvement is the choice of suitable varieties and a chapter is devoted to practical notes on the more important varieties in cultivation. The remainder of the book deals with the diseases of the crop, and this section, like the rest of the book, is excellently illustrated. The disposal of the crop and its position in commerce are also discussed. Many references to the literature are given and the book is well indexed. H. V. G.

(1) *Worsted Open Drawing: a Simply Written Explanation of the Process; for Managers, Foremen and Students in the Industry.* By S. Kershaw. Pp. vii + 131. (London: Sir Isaac Pitman and Sons, Ltd., 1931.) 5*s.* net.
(2) *Leather Crafts Manual.* By Ivy Evelyn Norman and Paul I. Smith. (Lockwood's Manuals.) Pp. vii + 88. (London: Crosby Lockwood and Son, 1930.) 2*s.* 6*d.* net.
(3) *Practical Dry Cleaner, Scourer and Garment Dyer.* Edited by William T. Brannt and J. B. Gray. Sixth corrected edition. Pp. xviii + 378. (London: Crosby Lockwood and Son, 1930.) 12*s.* net.

IT is always matter of conjecture as to the kind of reader to whom technical works will hold an appeal. Class students will use the textbooks recommended by their teachers; the majority of craftsmen may well carry on without such books (Does not Mr. Kershaw write, in (1), p. 75, "Intelligent working is better than a guide book"?), whilst the general reader will mostly ignore technical works; (3) is an exception to test the rule, for it seems to interest the public and is now in a sixth edition. Truly, the essential merits of these three books are independent of general favour, however such limitation might be disapproved by the publishers. Once again, as so very often, are we confronted with the view ("Worsted Open Drawing", p. 85): "Even experts disagree". Mr. Kershaw's work is commendably practical and has many useful diagrams. "The Leather Crafts Manual" is brief and to the point; it may, however, be remarked, regarding the historical survey, that assumptions are not proofs. The text is full of interest and the illustrations are attractive, but the index is very poor. (3) is far too diffuse in treatment, and however accurate the text, yet the impression conveyed is as of a *catalogue raisonnée* of recipes, with not infrequent repetition of information. Sufficiently pruned, there would be enough left to satisfy requirements; but the treatment is due probably to the book being a compilation by various writers.

P. L. M.

Index of Spectra. By the late Dr. W. Marshall Watts. Appendix Z: *Iron and Iron Oxide.* Pp. 116. (Westcliff-on-Sea: T. M. F. Tamblyn-Watts, 1931.) 18*s.*

WATTS'S "Index of Spectra" was a household name among the last generation of spectroscopists, and few books have in their day fulfilled more adequately an important purpose. Mr. F. Tamblyn-Watts, who was Dr. Watts's assistant for more than thirty years, and to whom have been left the papers which were to have formed the basis of a continuation of the "Index", has decided to publish these papers as they stand, as additional appendices. They contain material up to 1918 relating to some twenty elements and certain of their compounds, and the volume before us is one of the posthumous publications. Those familiar with Watts's "Index"—that is to say, all the older spectroscopists—will need no description of the character of the work.

We cannot but regret that Mr. Watts has ventured to continue the publication of this work. Invaluable as the "Index of Spectra" has been in the past, its work is done. Modern spectroscopy requires something different, and this is being adequately supplied in the seventh volume of Kayser's "Handbuch der Spektroscopie", which is now appearing part by part. The new appendix dealing with the iron spectrum is particularly inopportune, since iron provides the secondary and tertiary standards of wave-length and has accordingly received special attention during the last decade. At the time when the measurements here published were made the importance of 'pole effect' was unknown! Mr. Watts would be well advised to abandon his project, which must inevitably fail to achieve the purpose he has in view.

Handbuch der Spektroscopie. Von Prof. H. Kayser und Prof. H. Konen. Band 7, Lieferung 2. Pp. 499-750. (Leipzig: S. Hirzel, 1931.) 28 goldmarks.

THE seventh volume of Kayser's standard "Handbuch der Spektroscopie" is devoted to bringing up to date the collection of data which vols. 5 and 6 provided for an earlier period. In this great task Prof. Kayser has the collaboration of Prof. Konen, and the first part of the new volume appeared in 1923. It contained data for the elements A to Fe (in alphabetical order of chemical symbols) complete up to 1922. The long interval which has elapsed before the publication of the second part of the volume is due to the magnitude of the task and pressure of other work. The second part now before us treats of the elements Ga to Ir, but includes only data up to 1928. In order so far as possible to preserve homogeneity of the whole volume with respect to the period covered, it is proposed in the third part, which is now nearly ready, to summarise subsequent work on the elements A to Hf up to the time of publication. The remaining parts will then appear as quickly as possible and will be complete to date of issue.

The new part, in which 250 pages are necessary to present the work on ten elements, has the well-known characteristics of this invaluable book, and no description will be necessary. The deep debt of gratitude which spectroscopists have for long owed to Prof. Kayser (and for the present volume to Prof. Konen also) will be increased by this new publication, and the forthcoming parts will be eagerly awaited.

A School Algebra: as far as the Advanced Course in the School Certificate Stage. By A. M. Bozman. Pp. viii + 427 + lxii. (London and Toronto: J. M. Dent and Sons, Ltd., 1931.) 4*s*. 6*d*.

THIS textbook is designed to cover a school course in algebra up to the stage of the advanced papers in school certificate examinations. It is divided into two parts, the first comprising twelve good chapters on the fundamentals, and the second an additional thirteen chapters on the progressions, surds, logarithms, theory of quadratics, graphical solutions, permutations, combinations, and the binomial theorem.

The general plan of the course is well laid out, though the chapter on generalised arithmetic might have come a little earlier. Very commendable features are the changing of the subject of a formula and the graphical treatment of equations. The former is too often inadequately dealt with in many existing textbooks in spite of the fact that a knowledge of the fundamental processes of algebra is demanded, whilst the latter is frequently vitiated by piecemeal treatment, which tends to obscure the real significance of graphical representation. In the present volume these defects have been skilfully remedied; the chapter on graphical solutions being particularly clear and thoroughly sound.

Each chapter contains a good assortment of interesting and well-graded examples, though a few seem rather difficult, for example, Nos. 11 and 13 on p. 251. There are also five sets of excellent revision exercises, the last of which, beginning on p. 413, should be announced in the list of contents on p. vi.

The volume may be favourably commended to all who need a good book on the subject.

Die Schlämmanalyse. Von Dr. Hermann Gessner. (Kolloidforschung in Einzeldarstellungen, herausgegeben von Herbert Freundlich, Band 10.) Pp. x + 244. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1931.) 18 gold marks.

MECHANICAL methods of analysis by elutriation, originally applied almost exclusively to soil analysis, are finding increasing value in the examination of many technical products. This book deals with particles ranging from 1 mm. to 0·001 mm. diameter, and is mainly concerned with sedimentation methods, although sieving and air separation are touched upon. The first third of the letterpress treats of the theory of the falling particle; the next third describes the apparatus used, and more than sixty types of sedimentation vessels are figured; the last third shows the practical applications of the methods. With such a host of different types of apparatus, all designed for the same purpose and differing only in detail, it is not easy to appreciate the various advantages and disadvantages. A greater measure of criticism might have been given, and comparison of results obtained with different types would have been instructive. The question of sieves receives rather scant treatment, and standard sieves other than German are not mentioned. Nevertheless, the book forms a worthy addition to the monographs on colloidal subjects of which it is the tenth volume. J. R. NICHOLLS.

The Passivity of Iron.

By U. R. Evans.

IN 1790, James Keir[1] discovered that treatment of iron with nitric acid produces a peculiar condition in which the metal loses its power of precipitating silver from silver nitrate, although retaining its 'metallic splendour'. The behaviour of iron towards nitric acid was further examined by Schönbein[2] and Faraday;[3] Schönbein described the peculiar condition as 'passivity'. Later work has shown that many other oxidising agents render iron passive towards reagents which attack the metal in its ordinary or 'active' condition; reducing agents tend to restore 'activity'. Similarly, anodic treatment may produce passivity, but cathodic treatment usually renders the metal active again. Low temperatures favour continuation of passivity, and high temperatures a return to activity; alkalis are favourable to passivity, and non-oxidising acids to activity. These facts cannot fail to suggest that passivity is due to a protective oxide film.

The objection has been raised that passivity can be produced under conditions where an oxide film would be dissolved. Recent work, however, has shown such statements to be untrue. Furthermore, the oxide films responsible for the principal types of passivity have now been stripped from the metal and studied; although invisible when in optical contact with the bright metal, the films are perfectly visible when lifted from it. Finally, optical methods have been worked out which enable the invisible film to be detected whilst still upon the metal; such methods depend on the manner in which a film affects the character of polarised light reflected at a metallic surface—a subject examined mathematically by Drude.[4] The cause of passivity is therefore no longer in doubt, and the time is appropriate to review the subject.

Passivity due to Nitric Acid.

Dilute nitric acid consumes iron far more rapidly than dilute sulphuric acid; but the concentrated acid produces only a feeble reaction, and even this soon dies away, the iron becoming passive; the iron may then be brought into acid sufficiently dilute to attack active iron, and yet will remain unchanged. It has been alleged that this type of passivity cannot be due to a layer of oxide, which, it is argued, would be destroyed by the acid. In 1928, however, Hedges[5] studied the action of nitric acid on ferric oxide (free from hydroxide), and found that there was practically no dissolution at low temperatures; when the acid was heated, dissolution set in at about 75° C., and this is roughly the temperature at which the passivity of iron, placed in nitric acid, breaks down. Thus, Hedges not only removed the objections to the oxide film view, but also produced new evidence in its favour. I have found it possible to keep flaky ferric oxide in nitric acid for six days without destruction of the flakes.[6] The film formed on iron by concentrated nitric acid is invisible, but, in 1900, Michéli[7] obtained optical evidence of its existence. Moreover, Benedicks and Sederholm[8] have shown that iron placed in dilute nitric acid containing alcohol develops a film which displays a network of cracks on drying; in this special case, therefore, the film becomes visible even when it is still attached to the metal. There is no reason to doubt that the passivity produced by nitric acid is due to an obstructive film of ferric oxide.

Passivity produced by Exposure to Air.

Pilling and Bedworth[9] have divided metals into two classes, according to the relation between the densities of the elements and their oxides. In the first class, the natural volume of the oxide is less than the volume of the metal needed to produce it; here any superficial oxidation will necessarily produce an oxide layer pierced by voids through which oxygen can pass unobstructed to attack the metal below. This class includes most of the lighter metals, such as magnesium and calcium, and it is not surprising to find that those metals 'burn' readily in air. Iron and most other heavy metals belong to the second class. Here, the oxide, when unstressed, occupies a greater volume than the metal contained in it. Consequently, conversion of the surface into oxide will produce a layer free from voids, which is actually in a state of lateral compression.

At ordinary temperatures, such a film, even when very thin, should exclude oxygen from the metal below, and thus the film on iron exposed to dry cold air never attains 'visible thickness'. At slightly elevated temperatures, diffusion of oxygen through the solid film becomes possible, and the film may reach a thickness comparable to the wavelength of light, so that interference tints appear on the metal; at still higher temperatures, a thick greyish scale is produced, which often tends to crack and peel off.

This cracking and peeling is very characteristic of relatively thick films. It is partly attributable to differences in the coefficients of expansion of iron and its oxide; but probably even if produced and held at constant temperature, a thick film would tend to crack more than a thin film. All films formed on heavy metals must possess potential energy due to the state of compression, which energy will be released when the film becomes detached. Thus, the work needed to detach area a of an ideal film of thickness θ will not be less than $aW_A - a\theta P_C$, where W_A is the adhesional work per unit area and P_C the compressional energy per unit volume (work against cohesional forces is neglected, being small for a thin film). When, therefore, the thickness θ is less than W_A/P_C, energy must be expended in stripping the film; but if the thickness is greater than that value, spontaneous peeling is at least not impossible. In the case of scale produced at a red heat, this spontaneous detachment can often be observed microscopically, whilst the ultra-microscopic cracking of films of the interference colour range is inferred from the fact that these films have a far smaller protective action than 'invisible' films, which are too thin to give colours. Electrolytic iron, if freshly abraded, quickly precipitates copper when a drop of dilute copper nitrate solution is placed on the surface. If the iron is exposed to air at ordinary temperatures for some time before the copper nitrate is applied, the deposition of copper does not occur; the time needed for the formation of a film sufficiently continuous for protection is much greater after coarse abrasion than after fine abrasion, doubtless owing to the internal stresses and ultra-microscopic fissures left in the metal in the first case. If the iron is gently warmed in air and cooled again, the passivity towards copper nitrate is produced more quickly than at ordinary temperatures; but if the warming has been conducted at temperatures where interference tints appear, deposition of copper commences, starting at points representing cracks in the film. Thus, if a strip of freshly abraded iron is gently heated for a few seconds at one end (the other end being unheated), cooled and tested with copper nitrate, the iron will usually be found active at the unheated end, where the film is incomplete, and also at the heated end, where it is cracked; but there will generally be a passive region in the gently warmed part in the middle.

There is little doubt that the nitrate itself has some film-repairing action, since copper sulphate usually produces some deposition of copper under analogous conditions. Copper chloride invariably produces instantaneous growth of copper; chlorine ions can penetrate through imperfections which the larger ions cannot pass.[10] Even in copper nitrate the passivity of iron often tends to break down at jagged places. This failure is to be expected; geometrical considerations indicate that, at points of high convex curvature, the metallic atoms will, on oxidation, move outwards to a circle of greater radius, so that the lateral compression already referred to will be abnormally low at these points.

Steel or commercial iron does not attain reliable passivity on exposure to air alone; the junction between dissimilar phases constitutes a place where a protective film is liable to break down. But if steel is treated in a solution of chromic acid or potassium chromate the weak places are brought into repair, and a drop of copper nitrate afterwards produces no action.

In recent papers which I have published,[11] with J. Stockdale, L. C. Bannister, S. C. Britton, and other collaborators, methods are described for isolating oxide films from a metallic basis. All methods depend on an operation, such as immersion in iodine, or anodic treatment in a chloride or sulphate solution, which dissolves the metal just below the oxide film; this allows the oxide film to peel off or to be transferred to glass or cellophane. In the case of some metals, particularly nickel, the films responsible for heat-tints themselves show bright colours after removal. The protective films on iron made passive by exposure to air at low temperatures, being too thin to give colours, are invisible whilst on the bright metallic surface; but they are found to be plainly visible when removed from it. Being thinner than the films from heat-tinted iron, they are, as a whole, more transparent; but since there is more interlocking with the metal when the film is thin, the 'passivity films' show frequent opaque spots due to residual metal. A comparative study of films above and below the limiting thickness needed to produce colour (about 400 A.) has indicated that no sharp change of properties occurs at the limiting thickness, the position of which is merely fixed by the accident that the human eye is insensitive to waves below a certain wave-length.

The thinner (invisible) films have been detected optically whilst still on the metal by Freundlich, Patscheke, and Zocher,[12] whose conclusions agree with the results of the Cambridge experiments in indicating that combination of iron with oxygen occurs rapidly even at room temperature, although the films cease to grow before they reach visible thickness.* A pure iron mirror free from oxide was obtained by heating iron carbonyl vapour in a closed vessel. When air was admitted and quickly pumped out again, an oxide film was left on the metal which could be detected by the polarised light method; simultaneously the mirror became inert to nitric acid of specific gravity 1·4, although similar mirrors not exposed to air were attacked by the acid under identical conditions. The optical change corresponded to a mean film-thickness of about 10 A. The films produced on abraded surfaces at Cambridge are very much thicker, since the abrasion produces a zone of disorganised metal, and the oxygen can penetrate more deeply. These thicker films are actually less protective than the very thin ones; but to the experimenter the thickness is useful, since it allows the film to be removed from the metal.

PASSIVITY PRODUCED BY ANODIC TREATMENT.

The fact that an iron anode becomes passive in an alkaline solution is easily understood on the oxide film view. But anodic passivity can also be produced in a neutral salt solution, or even (if the current density is high enough) in dilute acid. When iron is made the anode in dilute sulphuric acid at a low current density, it passes smoothly into solution as ferrous sulphate. When the initial current density is high, dissolution also occurs normally at first; but later passivity sets in, the dissolution slows down, and the current sinks to a lower value The current, which continues to flow in the passive state (providing the e.m.f. is high enough), is mainly devoted to the production of oxygen gas; the dissolution of iron, although still measurable, becomes very slow.[13]

W. J. Müller [14] has shown that the time needed to produce passivity becomes shorter as the initial current density is increased; he has also demonstrated that passivity never sets in until the liquid layer next to the metal has become saturated with some iron compound; indeed, at this stage the polarising microscope has revealed some solid substance, apparently $FeSO_4,7H_2O$, upon the metallic surface.[15] It is unlikely, however, that a layer of ferrous sulphate is directly responsible for the passivity;[16] for all visible material present on the iron surface peels off or disappears when complete passivity sets in, a circumstance noticed by Hedges.[17] When once oxygen evolution has begun, the metal is clean and bright, and the passivity is certainly due to an invisible oxide film on the surface. This film has recently been detected and measured optically in an important research by Tronstad,[18] who has followed the increase of film thickness under anodic treatment, as well as the diminution under cathodic treatment, in acid, neutral, and alkaline solutions.

---

* Some evidence of the very rapid oxidation of iron in air at low temperatures was provided by Faraday in his "Experimental Researches in Electricity", Series XVII. § 2049 (1840). I am indebted to Mr. A. Marshall for directing my attention to this work.

Probably authorities would still differ regarding the details of the anodic reactions. When the iron is active, the discharge of sulphate ions to give ferrous sulphate may conveniently be written thus:

$$SO_4'' + Fe = 2e + FeSO_4.$$

The ferrous sulphate will at first dissolve in the liquid, regenerating SO_4'' ions; but at high-current densities the liquid layer will soon become supersaturated, and solid matter will separate out, covering up most of the surface, and raising the true current density on the small part still uncovered. This may permit the local potential to rise high enough for the inception of alternative reactions, which absorb greater amounts of energy. For example, the discharge of hydroxyl ions, according to the equation

$$2OH' = 2e + H_2O + O$$

becomes quite possible at this stage, since the hydrogen ion concentration of the layer next the anode is now greatly decreased. The oxygen may convert the iron superficially into oxide, which will interfere with further conversion of iron to sulphate; but the major part of the oxygen will stream off as oxygen bubbles, which will dissipate the visible crust of ferrous sulphate or basic salt, and leave only the invisible oxide to protect the metallic surface.

I have investigated the objection that sulphuric acid would dissolve a ferric oxide film,[19] commencing by studying iron covered with a visible ferric oxide film. Iron heated in air to give an early interference tint (caused by a film of 500-800 A. thickness) was cooled and introduced into $M/10$ sulphuric acid; within a second, the film was dissolved away and the colour vanished. The experiment was repeated with iron heated to give thicker films (greater than 2000 A.); here there was some slight attack at first, but the films soon peeled off, and, as soon as the oxide was out of contact with the metal, the dissolution practically ceased; the film flakes could then be collected, washed, and photographed. This shows that sulphuric acid has practically no *direct* action on ferric oxide; the rapid destruction of the film in contact with metal is due to the cell

Iron | Sulphuric Acid | Ferric Oxide

set up at discontinuities; the ferric oxide is the cathode of this short-circuited cell, and becomes reduced to ferrous oxide, which at once dissolves in the acid; it seems that oxides of the type MO are usually much more quickly attacked by acid than those of the type M_2O_3. This explanation is supported by the fact that if chromic acid, a strong oxidising agent, which would prevent the reduction, is added to the dilute sulphuric acid, heat-tinted iron can be kept in the acid mixture for many hours without loss of colour.

Heat-tinted iron was then subjected to anodic treatment in $M/10$ sulphuric acid (the e.m.f. and resistance being such as to provide a current density of 6 amp./dm.^{2} when the iron was active, or 3 amp./dm.^{2} when it was passive). It was found that if the tinted iron was introduced into the acid before the circuit was completed, the colour film was destroyed, and when the current commenced to flow, the iron behaved as an active electrode, passing into solution as ferrous sulphate. But if the circuit was completed before the introduction of the anode, so that the current flowed from the instant of immersion, then the iron was passive from the first moment, and oxygen was evolved, the colour due to the film remaining undestroyed. It was then possible to interrupt the current for a few seconds without destruction of the film; during the interruption a few oxygen bubbles continued to rise from the metal, indicating a residual charge of excess oxygen, which doubtless prevented the local reduction to the quickly soluble ferrous compound. If the circuit was restored before this supercharge of oxygen was exhausted, the iron was still found to be passive, oxygen was again evolved freely, and the colour remained undestroyed. But if the interruption was continued after the bubbles representing the supercharge had ceased to appear, then the oxide film was destroyed by the mechanism already indicated, the colour vanished, and, on restoring the circuit, the iron was active, and dissolved freely without any appearance of oxygen. If the circuit was restored at the precise moment when the film had suffered destruction at some points but not at others, dissolution of the iron commenced at the film-free points, thence extending under the skin, which peeled off in curling flakes. When once these oxide flakes had passed out of contact with the metal, their dissolution ceased.

Experiments conducted on iron which had been exposed, after abrasion, to air at ordinary temperatures showed remarkable analogies with the results obtained on heat-tinted specimens; evidently, the thin invisible films behaved in much the same way as the thicker colour-films. When the current was turned on after the anode entered the acid, the iron was dissolved freely, whereas if the circuit was completed before the introduction of the anode, the iron was usually passive from the moment of immersion, oxygen being evolved from the surface. The current could then be interrupted for a few seconds without destroying the passivity, but if the interruption was prolonged beyond the short period during which the slow stream of oxygen bubbles (representing the supercharge) rose from the metal, then, on restoring the current, the iron behaved as an active anode, and iron passed freely into solution without evolution of oxygen. Special experiments,[20] in which the circuit was restored at a chosen moment when the film was destroyed at certain points but not at others, indicated that it was possible to undermine the invisible film formed during the previous passive period; it peeled off in curling microscopic flakes, which, although mechanically flimsy, were chemically stable in the acid, when once out of contact with metallic iron. Thus the films responsible for anodic passivity, like those responsible for air-passivity, have been stripped from the reflecting basis and rendered visible.

Space does not permit the discussion of several other aspects of anodic passivity, particularly the periodic alternations between the active and passive states which often occur at a range of current densities intermediate between the activity and passivity ranges. For this matter, the reader is referred to the work of Hedges,[21] who has made the subject particularly his own.

CONCLUSIONS.

It is not suggested that all inert metals owe their lack of reactivity to oxide films; metals like gold will react very slowly even when quite free from films. But the important types of passivity in iron are almost certainly due to films of ferric oxide. The facts as known to-day confirm in many respects the porous oxide film theory put forward twenty-five years ago by Haber and Goldschmidt.[22] All iron which has been exposed to air is covered with an oxide film; the essential difference between active iron and passive iron is that on the former the film is in bad repair and on the latter it is in good repair; the degree of initial repair needed to cause a sample of iron to display passivity will vary with the presence or absence of film repairers or penetrating ions in the solution into which it is to be introduced. A ferric oxide film will only resist the action of a non-oxidising acid, for example, dilute sulphuric acid, if a supercharge of oxygen is present to prevent local reduction to the rapidly dissolving lower oxide, or alternatively if an oxidising agent, for example, chromic acid, is also present; where the main acid is itself an oxidising agent, for example, nitric acid, this reduction does not occur.

I am indebted to Dr. L. Tronstad for much information embodied in this article.

The Voyage of the *Beagle*, 1831–1836.

ON Dec. 27, 1831, H.M.S. *Beagle*, a ten-gun brig, under the command of Capt. FitzRoy, R.N., sailed from Devonport. "The object of the expedition was to complete the survey of Patagonia and Tierra del Fuego, commenced under Capt. King in 1826 to 1830—to survey the shores of Chile, Peru, and of some islands in the Pacific—and to carry a chain of chronometrical measurements round the world." It is well known how FitzRoy proposed to the Hydrographer that "some well-educated and scientific person" should be invited to join the expedition, how Capt. Beaufort wrote to Prof. Peacock, that he in turn consulted Prof. Henslow, who, as FitzRoy writes, "named Mr. Charles Darwin, grandson of Dr. Darwin the poet, as a young man of promising ability, extremely fond of geology, and indeed of all branches of natural history".

The voyage lasted about three months short of five years. The first land touched was St. Jago, one of the Cape de Verd Islands. In the three weeks spent there, Darwin's observations had two most useful results. They showed him "the superiority of Lyell's manner of treating geology" in the first volume of the "Principles", in spite of Henslow's well-meant warning "on no account to accept the views therein advocated". It was there, too, that it "first dawned on me that I might perhaps write a book on the geology of the various countries visited, and this made me thrill with delight. That was a memorable hour to me."

From St. Jago the *Beagle* crossed the Atlantic, by way of the St. Paul's Rocks and Fernando Noronha, to Bahia in Brazil. Nearly three and a half years, from March 1832 to July or August 1835, were spent at various ports on the South American coasts from Bahia southwards to the Falkland Islands and Tierra del Fuego, and then up the west coast to Valparaiso and Callao. From the latter port the *Beagle* sailed westwards, with long stops in the Galapagos Islands, Tahiti, New Zealand, and Australia, then by Keeling Island, with its coral reefs, Mauritius, Cape Town, St. Helena and Ascension, and once more to Bahia, returning to England in the autumn of 1836.

During the long pauses at the various South American ports, Darwin made many an excursion inland. From Bahia Blanca he crossed the Pampas and dug out the remains of "great fossil animals covered with armour like that on the existing armadillos ", a discovery that he notes as one of the beginnings of his views on the origin of species. At Valdivia he felt the great Concepcion earthquake of Feb. 20, 1835, and his accounts of the earthquake in his " Journal " and in his important memoir on the volcanic phenomena of South America read before the Geological Society are among our chief authorities on this great disturbance.* On the west coast of South America, from lat. 45½° to 12° S., he found traces of shelves uplifted at various times to a height, as near Valparaiso, of 1300 feet. It was here also that the whole theory of the origin of coral reefs was thought out before he had seen a single true reef. The intermittent elevation of the South American coast led him to reflect on the effects of subsidence, replacing " in imagination the continued deposition of sediment by the upward growth of corals ".

No part of the voyage had so much effect on his subsequent work, however, as the five weeks spent in the Galapagos archipelago. The chapter on these islands was almost rewritten in the later editions. But there are a few sentences in the first edition, omitted from the others, that are worth reprinting, if only for what was evidently in his mind, though then left unexpressed. " It would be impossible for any one accustomed to the birds of Chile and La Plata to be placed on these islands, and not to feel convinced that he was, as far as the organic world was concerned, on American ground. This similarity in type, between distant islands and continents, while the species are distinct, has scarcely been sufficiently noticed. The circumstance would be explained, according to the views of some authors, by saying that the creative power had acted according to the same law over a wide area " (p. 474). He afterwards reflected " with high satisfaction " on the discovery of these relations; for it was evident, even in those early days, that such facts " could only be explained on the supposition that species gradually become modified ".

The *Beagle* reached Falmouth on Oct. 2, 1836, and, in the following December, Darwin was in Cambridge arranging his collections. At the same time he began writing his " Journal of Travels "; not hard work, he notes, for his MS. journal had been written with care. His chief labour was to make an abstract of his more interesting scientific results. In March 1837 he moved to Great Marlborough Street in London, and the " Journal " seems to have been finished by July, for in August he was unable to leave London as he was busily engaged in correcting the proofs. Possibly it was to celebrate the completion of the MS. that, in July 1837, he opened his " first notebook for facts in relation to the Origin of Species ", a subject on which even then he " had long reflected ".

Even so late as December of the same year there was evidently some idea of mixing the journal up with FitzRoy's, for his future wife then wrote that his sister " wants it to be put altogether by itself in an Appendix " (" Emma Darwin ", vol. 1, p. 274). This was the plan afterwards followed, and it appeared as the third volume of FitzRoy's " Narrative " under the title " Journal and Results ".

The " Journal " was one of the longest of Darwin's books, and it was begun and finished within seven months. This meant that he must usually have written nearly three pages a day. Copies of the proofs were circulated among various friends, for Hooker read Lyell's set before he left on his southern voyage and slept with them underneath his pillow. On the other hand, Dr. Holland thought they were not worth publishing, though " I don't believe ", wrote Darwin's future wife, " he is any judge as to what is amusing or interesting ".

When it did appear there was little doubt as to its reception. The copy that Lyell gave to Hooker became " a well-thumbed copy ", for all the officers in the *Erebus* were borrowing it. The second master of the *Terror* wrote that Darwin had " accomplished what Old Johnson said of Goldsmith when he heard he was going to write a Natural History, ' he will make it as interesting as a Persian tale ' ". Even the historian Sismondi was " found in an ecstasy over the book ". " Notwithstanding his ignorance of natural history he found the greatest interest in it, that it was written with so much feeling, so good, so right a heart."

The " Journal and Results " is in one way unique among Darwin's works. It is the only book of his that was written before he became a permanent invalid. It has all the charm of the health and vigour of youth; on nearly every page it reveals his delightful personality, his humour and never-ending courtesy. It is written in a style that is always fresh and interesting. It has inspired many similar works, and yet it remains, far and away beyond all others, the greatest of our books on scientific travel.

It owes this place no doubt to Darwin's habit of writing up his MS. journal day by day, taking pains to describe carefully and vividly all that he had seen. In after years Darwin often lamented his inability to write a simple sentence. There is no trace of this difficulty in the " Journal ", and page after page might be quoted as models of good clear English. There is one passage at least—the description of Brazilian forest scenery—that seems not altogether unworthy of a master of English prose. " I have said that the plants in a hothouse fail to communicate a just idea of the vegetation, yet I must recur to it. The land is one great wild, untidy, luxuriant hothouse, which nature made for her menagerie, but man has taken possession of it, and has studded it with gay houses and formal gardens. . . . In my last walk, I stopped again and again to gaze on these beauties, and endeavoured to fix for ever in my mind an impression, which at the time I knew, sooner or later must fail. The form of the orange-tree, the cocoa-nut, the palm, the mango, the tree-fern, the banana, will remain clear and separate; but the thousand beauties which unite these into one perfect scene must fade away; yet they will leave, like a tale heard in childhood, a picture full of indistinct, but most beautiful figures " (p. 390).

---

* On next April 19 it will be fifty years since Darwin's death, and we are still wanting : (i) a volume reprinting his memoirs (such as that mentioned above) and his other papers not directly reproduced in his books, and (ii) an index to all his works, like that compiled by Cook and Wedderburn for Ruskin's complete works.

The " Journal and Remarks " long survived the two volumes with which it was once connected. In the first three years 1337 copies were sold. A second edition appeared by itself in 1845 as one of the " Home and Colonial Library ". It was then called " Journal of Researches into the Natural History and Geology of the countries visited during the Voyage of H.M.S. 'Beagle', etc." The third edition, with the same title inside, but on the cover " Naturalist's Voyage round the World ", was published by Murray in 1860.* They were thus prepared in the years following the writing of the " Sketch " of 1844 and the appearance of the " Origin ", and they naturally contain more distinct references to his views on the modification of species. It is unnecessary to quote the changes made, for they are fully given in the " Life and Letters " (vol. 2, pp. 1-5). Of these two editions, many thousands of copies were sold—the imprint of 1879 is labelled " fourteenth thousand "—and translations have appeared in French, German, and other languages. In addition to the " Journal ", " The Structure and Distribution of Coral Reefs ", a book that he said " no human being will ever read ", was published in 1842, and a second edition in 1874. " Geological Observations on the Volcanic Islands, etc.", appeared in 1844, and " Geological Observations on South America " in 1846, and a second edition of both in one volume in 1876.

If it were only for these four books—and it was for the work contained in them and the Cirripede volumes that the Copley medal of the Royal Society was awarded to Darwin in 1864—we should be justified in recalling the departure of the *Beagle* a hundred years ago. But a still stronger claim lies in the observations that Darwin made on the Pampas, in the Galapagos Islands, and elsewhere in South America, the discoveries that were the foundation of the long course of reflection and experiment that ended in the " Origin of Species ".

* In 1901 a new edition was brought out with 15 plates and other illustrations

Obituary.

PROF. CARVETH READ.

PROF. CARVETH READ, whose death occurred on Dec. 6 at Solihull, was born at Falmouth on March 16, 1848. He counted among the contemporary philosophers who have been most influenced by science and scientific ideas. His early logical studies, which found their expression in an essay " On the Theory of Logic " (1878), are marked by what has been considered the Cambridge spirit, which insists on sound method, and is not satisfied with mere divination, even if it turns out to be true. His later well-known treatise, " Logic, Deductive and Inductive " (1898), of which the fourth edition (1914) is definitive, brought to a term his studies on that side.

A more speculative work was " The Metaphysics of Nature " (1905), where Prof. Read anticipates the later phase of thought that brings science and metaphysics into close contact. This phase, as has been pointed out sometimes in our columns, has made the old jokes about the futility of the pursuits of metaphysicians obsolete. To give science itself a firm standing-ground, as Prof. Read showed by setting himself to the task, metaphysical as well as logical distinctions are necessary.

Still, Prof. Read felt the influence of the prejudice, and owned that, " amidst the contempt into which ontology has now fallen it is lonely, wearisome, and depressing to write about it ". With an ironic humour for which he had a gift, he therefore turns in a self-deprecating manner on his own conclusions. These do, however, constitute a real construction, to which, as he has himself noted, Spinoza and Hume have in their different ways especially contributed.

In " Natural and Social Morals " (1909) Prof. Read went on to apply the conclusions arrived at, so far as they are applicable to human life. He had found that in a certain sense, with careful definitions, the world can be called a conscious being; though he also held that the interpretation of Nature, or of history, by final causes seems to lie beyond our power. But while we cannot say that consciousness, as it exists in the human mind, is the end of the universe, yet philosophy, or, to use a more generalised term, culture, is, in the old phrase of the schools, for man the Chief Good.

Evidently, however, theoretical knowledge as an end, whether in philosophy or in any other mode of activity, cannot be so predominant as to exclude all others. " To philosophise is not every man's ruling passion ", though thinkers like Aristotle and Spinoza placed it at the summit. The idealistic conclusion that " consciousness appertains universally to the unconditioned and perdurable Being ", Prof. Read regards as merely " orectic "; it is an effort to conceive rather than a definite conception. No use can be made of it in relation to the knowledge of phenomena. To those the thinker has to come back with only the guidance of scientific method.

Rather in the spirit of Hume, who, after all his subtle inquiries into ultimate questions, turned to something so tangible as history, Prof. Read took up finally as his special subject comparative psychology and the physical and mental evolution of man. The results are partly on record in " The Origin of Man and of his Superstitions " (1920; second edition in two separate volumes, 1925). With such positive scientific studies the years of Prof. Read's retirement from his successive chairs of philosophy and of comparative psychology in the University of London were occupied to the last.

News and Views.

ON Dec. 29 occurs the bicentenary of the death of Brook Taylor, who in his day was considered the most notable British mathematician after Newton, and who counted among his contemporaries Halley, Cotes, Saunderson, Colson and Maclaurin. Born on Aug. 18, 1685, at Edmonton, Middlesex, Taylor entered St. John's College, Cambridge, and in 1701, while there, began a correspondence with Keill of Oxford. He was elected a fellow of the Royal Society in 1712 and from that time onwards he contributed papers to the *Philosophical Transactions*, discussing the motion of projectiles, the centre of oscillation, and the forms taken by liquids when raised by capillarity. In 1715 he published his important work "Methodus Incrementorum Directa et Inversa", the first treatise dealing with the calculus of finite differences. It contained the famous 'Taylor's theorem', the importance of which was, however, not fully realised until pointed out by Lagrange. Taylor also published, in 1715 and 1719 respectively, two works on linear perspective which contained the earliest general enunciation of the principle of vanishing points. In 1714, he became one of the secretaries of the Royal Society, but resigned this post in 1718 and soon afterwards abandoned the study of mathematics. He long suffered from consumption, and he died at Somerset House on Dec. 29, 1731, at the age of forty-six years, two years after succeeding to his father's estate in Kent. He was twice married, his second wife dying in 1730, leaving him a daughter who married Sir William Young. Taylor was buried in the churchyard of St. Anne's, Soho.

AMONG the many vessels of the British Navy connected with the history of scientific exploration, H.M.S. *Beagle* will always be remembered on account of the work of her commanding officer, Capt. Robert FitzRoy, and of his famous guest, Charles Darwin, who, through Prof. Henslow, became FitzRoy's companion during five years. An account of the famous voyage which began on Dec. 27, 1831, appears elsewhere in this issue (p. 1065). FitzRoy had been appointed to the *Beagle* in 1828 at the age of twenty-three years, and already had made surveys of the coasts of Patagonia and Terra del Fuego. Though deeply interested in science himself, FitzRoy could not have foreseen what were to be the fruits of Darwin's studies. Darwin was invariably a sufferer from sea-sickness, the effects of which were felt all his life, yet he remained in the *Beagle* to the end of her voyage. From South America the ship crossed the Pacific, visited New Zealand, Australia, and the Cape, and arrived at Falmouth on Oct. 2, 1836. From the first there was a complete understanding between the commanding officer and his guest, and to FitzRoy is due the geographical names Mount Darwin, Darwin Sound, and Port Darwin. FitzRoy afterwards became governor of New Zealand, but he is also remembered for his work as chief of the Meteorological Office of the Board of Trade, and as a pioneer in the publication of weather forecasts. FitzRoy died in 1865, six years after Darwin's publication of his "Origin of Species", a work which was the direct outcome of Darwin's observations begun on the *Beagle*.

A TABLET has been placed on the house in Egerton Road, Bristol, where he lived for the last twenty-six years of his life, in memory of the late Mr. W. F. Denning, the veteran amateur astronomer and observer of meteors, who died on June 9. The tablet was unveiled on Dec. 18 by Dr. H. Knox-Shaw, president of the Royal Astronomical Society, in the presence of a number of Mr. Denning's relatives and friends. Prof. Lennard-Jones, who was present as the representative of the University of Bristol, referred to the fact that the University had conferred on Mr. Denning the honorary degree of M.Sc., and stated that he was a citizen of whom Bristol might well be proud. Dr. Knox-Shaw, in a short address, bore testimony to the high value set on Mr. Denning's work by his fellow-astronomers, and directed attention to the fact that the observation and study of meteors has of recent years come to be regarded as of much greater importance than in former days, partly owing to the information they afford as to the conditions at great heights in the earth's atmosphere.

DENNING'S catalogue of meteor radiants, published in 1899 in the *Memoirs of the Royal Astronomical Society*, still remains unique of its kind. In the later years of his life he calculated a large number of true meteor paths from observations made by himself and other people, many of whom were induced to cooperate with him by his evident devotion to his subject. He has left in manuscript a book on meteors which it is hoped will soon be published. An indication of the high standard of Denning's work is afforded by a letter which he wrote in the early 'seventies to the Rev. Robert Main, Radcliffe Observer at that time, requesting that the observations of meteors then being carried out at Oxford might be made with greater accuracy. His activities were by no means confined to meteors—he also made a series of valuable observations of the surface markings of the planet Jupiter—but it is because of his work on meteors that Denning's name will live in the foremost rank of English amateur astronomers. Mr. Denning was of an extremely retiring nature, and although he frequently wrote articles for the scientific journals and corresponded with a number of astronomers, he was personally known to only a very few. The inscription on the tablet runs as follows: "William Frederick Denning, F.R.A.S., Hon. M.Sc., Bristol University, and gold medallist of the Royal Astronomical Society, lived here from 1905 till his death on June 9th, 1931, aged 83 years. He discovered five comets and, in 1920, the new star in Cygnus, and was specially distinguished for his lifelong devotion to the observation and study of meteors."

ON Dec. 16 the new ore-dressing laboratory of the Mining Department of the University of Birmingham was opened by Sir Robert Horne. The Department already has a coal-treatment laboratory and a mining-machine laboratory (in which demonstrations of the use of coal-cutting and other machinery used in mines are given to students). This new extension therefore brings the state of equipment of the mining department to a standard probably unequalled in the world. At a luncheon which followed the opening ceremony, Sir Robert Horne insisted that "research, research, and research is the only policy upon which a thriving business can be founded". He believes that our coal industry is so far from being played out that in its future we shall find the renewal of prosperity of our country. There are great opportunities in low temperature carbonisation of coal on one hand and in hydrogenation on the other, and Sir Robert feels certain that scientific research to-day is on the edge of great discoveries. In both of these processes we have come very near to practicable results, and if the experiments which are being fruitfully made by an association of coalmasters in the Birmingham district are not misleading, "we may look forward with confidence to what the future of the coal industry is going to be". Sir Robert also believes that while large liners will keep to the use of oil fuel, a large part of the mercantile fleet will in future be run on pulverised coal.

AT the degree congregation which followed the luncheon, the honorary degree of LL.D. was conferred on Sir Robert Horne and Mr. Evan Williams. In introducing the former, the vice-principal (Prof. E. de Selincourt) said: "A University which believes in knowledge not only as worthy to be pursued for its own sake, but also as the one sure foundation for successful achievement in all branches of human activity, delights to honour those men who, prominent in the larger world of practical affairs, pay willing tribute to the intrinsic value of higher education and the vital importance of scientific research". In introducing Mr. Evan Williams, the vice-principal referred to the special effort which Mr. Williams has made to attract into the coal industry men of a high type: "We at this University hold him in special honour because he has always recognised that the success of the industry he controls depends ultimately on its power to draw into its ranks men of brains and character, who bring to their work no mere smattering of technical knowledge but a wide outlook and a scientifically trained intelligence; and because he has given a timely and practical encouragement to those researches which can only be conducted in the laboratory of the expert investigator".

SIR DANIEL HALL's thoughtful and moving article on "The Faith of a Man of Science" in the December number of the *Nineteenth Century* is a welcome sign of the times. Short as it is, it touches on a number of the deepest questions which are exercising all thinking men, and does it in a sincere and simple way which is the most effective for the purpose. It has often been remarked that the modern conferences of men of science have taken the place for us of the medieval conferences which discussed theology. But, with all their faults, the medieval conferences did go to the root of the matter; they discussed the subjects which at that time men thought the most fundamental. With us the scientific conference tends to be more and more specialist and technical, and we have to look to the individual to tell us what he thinks about first principles. More of them are coming to do this, and we may now add Sir Daniel Hall to the list on which Sir Oliver Lodge, Sir Arthur Eddington, and Prof. Julian Huxley are conspicuous names.

SIR DANIEL is alone among those mentioned in deriving his religion from the study of Berkeley, but in this he agrees with a large number of philosophical thinkers who are returning to Berkeley with added interest and pleasure. He is the fountain of the belief in modern times that the one reality is mind, and it is well known that recent extensions of our view of the universe, so far from dwarfing the mind of the thinker, have given a fresh range to the Berkeleian conception. The side on which one would have wished Sir Daniel Hall to have developed his thought is that of the collective mind, especially as exhibited in the history of science. No individual thinker, least of all the man of science, can expect to evolve a religion, or a coherent view of the whole, from his single consciousness. He needs to keep widening it to embrace the whole thinking process, back to the beginning of thought, and infinite, as it seems to us, in both directions. But it is a process in time, of which, for our own small part, the events are becoming more and more distinctly known.

"ACADEMIC Research and National Dividends" was the very topical alternative title given by Sir Frank Smith, secretary of the Department of Scientific and Industrial Research, to his Gluckstein Memorial Lecture entitled "Chemistry and the Community", delivered at the Institute of Chemistry on Dec. 18. Pure research, he said, has played a large part in the birth and development of most modern industries. Aluminium was exhibited in 1885 as a laboratory curiosity, but now a quarter of a million tons are produced yearly, chiefly by electrolysis, while the rare metals are the basis of many important engineering developments. Physical research on atomic structure and the nature of radiation, perhaps the most outstanding work of the present day, may seem far removed from practical affairs, but already it has given us the wireless valve, which has revolutionised communications, and the gas-filled tungsten lamp, with an efficiency four times that of the old carbon filament lamp. Sir Frank stated that such pure research in the past twenty-five years has led to a saving of not less than a thousand million pounds, and no one can foresee its further possibilities. As an indication of directions in which pure research can render further aid to industry, he mentioned lubrication, distillation of coal, alloys of iron and steel, and vulcanisation of rubber, all familiar subjects industrially but none of them fully understood. Tremendous advances would result from complete knowledge of the mechanism of these processes. The least depressed industries of the present time are those which maintain efficient research services. Work of this kind pays industry handsomely, and pays the community even better.

SOME important facts on the distribution of urban population in Great Britain were noted by Prof. C. B. Fawcett in a lecture to the Royal Geographical Society on Dec. 7. Using the term conurbation for the large urban areas, Prof. Fawcett showed that there are seven of these with a population of more than a million each, and that during the intercensal period 1921–31 the combined population of these areas has increased by 6·5 per cent, while that of the total population of Great Britain has increased by only 4·7 per cent. The population of the thirty next largest urban areas increased by 4·4 per cent, and that of the next thirty-eight towns by only 2·6 per cent. Thus the great conurbations have absorbed a considerable share of the total increase in population during the last decade. Of the total increase, greater London has absorbed about one half and greater Birmingham more than a sixth. Other interesting facts emerged from the county figures. These show that the gain in population is almost entirely confined to the English lowland. The 'highland areas' and the Isles of Man and Wight show actual decrease. The metropolitan area of London and its satellite towns has now a population of about twelve millions.

IN *Mechanical Engineering* for November is a biographical sketch by Mr. and Mrs. H. P. Vowles of Jacob Perkins, who was undoubtedly the pioneer in the use of very high pressure steam. His experiments extended over many years, and between 1820 and 1830 he constructed boilers and engines working at pressures of 800-1400 lb. per sq. in. One of his inventions was the precursor of what to-day is known as the uniflow engine. Perkins was born in Newburyport, Mass., on July 9, 1766, and was apprenticed to a goldsmith. He then turned his attention to the making of dies for copper coinage, machinery for nail making and for bank-note engraving. It was this last which brought him to England. The Bank of England would have nothing to do with Perkins' inventions, but he was successful in other directions and, in his later years, the firm he founded printed the first penny postage stamps. Ventilating and heating, steam-guns, paddle wheels, and other things all engaged Perkins' attention, and in 1826 he read a paper before the Royal Society describing his experiments on the compressibility of water, in which he used pressures up to 2000 atmospheres. As an American, he was regarded with a certain amount of jealousy, and by some was looked upon as a charlatan, but the present paper should remove any doubt as to the value of his work. He died in London on July 30, 1849, at the age of eighty-three years. His second son, Angier March Perkins (1799?–1881), and his grandson, Loftus Perkins (1834–1891), were both well known for their work with high pressure steam and hot water, and the latter was responsible for the machinery of the yacht *Anthracite* which in 1881 crossed the Atlantic fitted with a water-tube boiler with 500-lb. steam pressure. A great grandson, Ludlow Patton Perkins, who died in 1928, carried on the traditions of the family, while the firm of bank-note and stamp engravers, Messrs. Perkins, Bacon and Co., of Southwark Bridge Road, recalls the name of Jacob Perkins himself and of Joshua Bacon, a printer who married his daughter.

MANY engineers ten years ago deprecated the use of aluminium for overhead conductors on the grounds of its comparatively small tensile strength and that its weather-resisting qualities had not yet withstood the test of time. Since then the use of steel-cored aluminium has become almost universal. In this cable, the inner core generally consists of seven strands of galvanised steel wire twisted together, surrounded by a layer of aluminium wires twisted together, which forms a water-tight covering for the core. In this way a mechanically strong and electrically good conducting cable is obtained. The steel core provides the necessary tensile strength, and the aluminium carries most of the current. In the *Electrician* for Nov. 27, E. T. Painton points out the great demand there is for this kind of cable. The five chief factories in Great Britain are manufacturing it at the rate of 150,000 miles of cable per year. A large fraction of this cable is used for the national grid, but much of it is exported. In France the extensions of railway electrification and the development of water-power resources have led to great extensions of the overhead system, the bulk of which is carried out by steel-cored aluminium. In the United States, in Canada, and in Australia many new lines are being erected and the old lines duplicated by this kind of cable. Until its advent, span lengths of 1000 feet were only used in crossing rivers and ravines. It is now quite customary to use 1000-feet span lengths. The distance apart of the lattice towers in the Grampian Supply System varies from 900 ft. to 1300 ft. One of the greatest difficulties the engineer has to overcome is the obtaining of wayleaves, and the fewer towers required the easier it is to get them.

IN the annual report of the North-East Coast Institution of Engineers and Shipbuilders it is stated that the standard and volume of the discussion of papers have been well maintained, and the average attendance has been appreciably higher than for a number of sessions past. The membership roll now stands at 1201; but the Institution has to deplore the loss by death of twenty-four members, among whom are Sir Charles Parsons, Mr. Andrew Laing, Sir Hugh Bell, and Sir Archibald Ross. One interesting note in the report states that, as a result of the efforts of the Institution, the Newcastle-upon-Tyne City Council decided on May 20, 1931, to establish an engineering museum. The president of the Institution for 1931 is Mr. J. McGovern, now holding office for a second year, who delivered his presidential address on October 16. Dealing with the importance of technical knowledge and research, he asked the question whether a central research station controlled by the shipbuilding industries and free from direct government control would not be to the interests of the industries. He would include in the programme not only problems of resistance in air and water, propulsion, stability and rolling, but also investigations on vibration, stresses and deflections at sea, the impartial recording of trials and other problems, the solution of which demand resources not at the service of the majority of private firms. Regarding the best interests of the industry as a whole, "and further, as a general truth, we gain more by conference than by competition". In referring to the use of heavy oil engines in ships, Mr. McGovern spoke of the pioneer work of Akroyd—this, of course, should read 'Akroyd Stuart', 'Akroyd' being Stuart's Christian name.

THE Empire Marketing Board has issued a report, compiled by Sir William Dampier, on "Dairy Research" (E.M.B. No. 44. London: H.M. Stationery Office. 1*s*. net). The subject is dealt with under three headings: (1) What is dairy research, and what is the dividing line between a dairy research institute and other research institutions in the sphere of animal nutrition and diseases, and low temperature research? (2) What is being done in this field? and (3) What extensions are desirable, and to what problems should research be directed? A new system of payment for milk is advocated, on a basis of quality instead of volume. A further study of the detection of adulteration by freezing-point methods is recommended. As the consumption of milk per head of population in Great Britain is low, a publicity scheme for milk would, it is suggested, greatly benefit the industry. Attention is directed to some of the important practical results that have emerged from research work, such as Major Dunkin's test for the detection of Johne's disease; and further problems needing investigation are suggested—for example, the influence of pasteurisation on the vitamins in milk, the keeping and ripening of dairy products, the utilisation of by-products, inheritance of high milk yield, and many others.

Two developmental tendencies in connexion with the bird sanctuaries in the Royal Parks of England are noticeable in the Report for 1930, issued by H.M. Stationery Office. The first and most natural and proper tendency is towards the encouragement of native British birds, for nesting or for shelter and food. This has been brought about through the thinning of undergrowth, the planting of bushes suitable for cover and for their yield of berries, and by the suppression of vermin, amongst which the introduced grey squirrel is reckoned one of the greatest menaces. The most striking natural visitor of the year was a white stork which paid a spring-time call at Richmond Park. The second tendency is making the Royal Park sanctuaries something quite different from a bird sanctuary as generally understood. It is marked by the introduction of various sorts of foreign birds, with the intention that they should establish themslves and multiply. There have been added to the waters of the sanctuaries mandarin ducks, black-billed tree ducks, Baikal teal, Japanese spotbills, and Magellan geese, and in the shrubberies Indian doves, Amherst pheasants, and others—interesting birds all of them, and many beautiful, but a little suggestive of a zoological garden rather than a sanctuary for the encouragement of native birds and bird visitors.

THE sixteenth annual report (1931) of the Experimental and Research Station at Cheshunt, under the direction of Dr. W. F. Bewley, is a record of very varied activities, many of which have considerable general interest. Manurial trials and soil sterilisation trials are reported upon, steam sterilisation proving more successful than formaldehyde in practice, whilst P. H. Williams has continued the determination of the numbers of bacteria in the soil at weekly intervals. The presence of organic nitrogen seems to be the main factor determining the large and rapid fluctuations of bacterial content noted during the season. T. Small has continued the study of the tomato leaf mould, *Cladosporium fulvum*; the freeing from infection of empty greenhouses seems possible by fumigation under certain ideal conditions, but the incidence of the disease in practice obviously provides numerous puzzles, and considerable difficulties seem to stand in the way of its control by fungicide sprays or fumigants under commercial conditions. Interesting experimental results with several virus diseases are described. Attention may perhaps be directed to the frequent isolation of a bacterial organism from necrotic tissues by Bewley and Corbett, and to the simple and very effective methods of experimental inoculation of mosaic disease employed by B. D. Bolas. An ingenious experimental device for the study of soil ventilation described by the latter worker may also prove to have wide applicability, whilst the attempt to use electric light to rear hardy tomato seedlings during the winter months will be of special interest to northern readers.

NORTH country naturalist activity is shown in a very favourable light by the November issue of the *Vasculum* (vol. 17, No. 4). The news of societies reported in its pages shows local societies with an active membership, and with both field and indoor meetings able to supply reports of genuine interest, whilst some of the contributors' notes show how inquiries of very general interest are raised by such meetings. Thus the Darlington and Teesdale Naturalists' Field Club held its fungus foray this year at Dryderdale, and Mr. F. A. Mason, of Leeds, who undertook the task of identification, had as a result a list of 138 species and varieties. This autumn it has been a very general experience in the British Isles that the larger agarics are relatively scarce, but at Dryderdale they were found relatively in abundance. J. B. Nicholson contributes a suggestion based upon the abundance of toadstools in this locality compared with their poor appearance this season in the Darlington district. Usually their relative scarcity this autumn is put down to the poor growth of the mycelium during the inclement summer. Dryderdale is at a higher altitude than Darlington, and is not likely to be appreciably warmer. Mr. Nicholson suggests that a more important factor may have been the good drainage in this locality, and that a reason for the scarcity of such fungi may be, in some cases, the high water-table during the wet summer.

SIMILARLY, the editor of the *Vasculum*, the Rev. J. E. Hull, has a very interesting note, as the result of his collection of spiders during this wet summer, upon a possible association between melanism and humidity. The other articles, beside including valuable new records, as of the mosses, liverworts, and sphagna of South Northumberland, by E. M. Lobley, and upon a new genus and species of feather-mite (*Hirstia chelidonis*, J. E. Hull), also include two papers of considerable general interest. W. K. Richmond discusses the overland migration of wading birds in England, whilst J. E. Hull discusses a very interesting recent French paper by Jacques Denis, upon the spiders found in the coal mines of the north of France. The editor discusses, in charming but critical fashion, and with a recollection of earlier English records, the puzzles of distribution provided by the presence of some of these spiders living and breeding in the depths of the mine. Most of them have probably been introduced in the bark of the timber carried down the mine, but how does a species of *Theridion* arrive and flourish there when its normal habitat is the greenhouse, and it has never been taken in the open air in the north or centre of France ?

WE learn from Science Service, Washington, D.C., that attention is being given to the problem as to whether the yellow fever mosquito and other kinds of similar insects are likely to be carried to the United States through the agency of long-distance aeroplanes. Members of the United States Public Health Service have found that certain types of aeroplanes do carry mosquitoes. Stained examples of the insects were liberated into planes leaving Porto Rico and a certain number were recovered when the machines arrived at Miami, 1250 miles away. Heavy infestation of planes at airports is not considered likely, but even one infected mosquito, of the yellow fever kind, might be the means of starting an epidemic. Considering the small number of these insects that find their way into aircraft, and the facility with which the latter may be freed, it is concluded that while the danger does exist, aeroplanes can be efficiently treated so as to destroy mosquitoes. Air traffic development need not therefore be delayed on this account.

AN interesting institution, known as "La Clinique-Manufacture Internationale", at Leysin, Switzerland, is described by Dr. Rollier, the director of heliotherapy there, in *Bull. Soc. d'Encouragement pour l'Industrie Nat.*, Nos. 7, 8, 9; 1931. This Institute is devoted to sun treatment of cases of surgical tuberculosis, the patients while under treatment being engaged in regular and remunerative work. This is accomplished, for example, by the use of trolleys provided with electric motors and such tools as may be required, which are wheeled to the bed and adjusted to the needs of the particular person. We see depicted in the illustrations, patients in bed, but fully exposed to the sun's rays—basket-maker, sculptor, needle-woman, lace-maker, and mechanics—at work at their crafts ; spinal cases lying in the prone position. The Institute, a fine building looking out to the Dents du Midi, was opened in February last year and has 120 beds.

WE have received from the Ministry of Agriculture and Fisheries a copy of an illustrated Bulletin, No. 29, entitled "Insect Pests and Fungus Diseases of Basket Willows", 1931. Few plants are more subject to insect attacks than are willows and osiers, while fungus diseases are, on the whole, less numerous. This Bulletin describes the principal pests involved, whether they be insect or fungus, and the control measures that are appropriate in each case. It is a publication of definite practical utility, and growers should make use of the information that it brings together. The heaviness of insect infestation is often a serious drawback to osier cultivation, but with the present Bulletin in his hands, the grower should be able to surmount such difficulties. It is priced at 6*d.* net, and is obtainable from His Majesty's Stationery Office, or through any bookseller.

THE Lord President of the Council has appointed Dr. F. S. Sinnatt, M.B.E., to be director of fuel research under the Department of Scientific and Industrial Research.

THE triennial award of the Coopers Hill War Memorial Prize and Medal, which fell in 1931 to the Institution of Electrical Engineers, has been made by the Council to Dr. M. G. Say, for his paper on "High-Voltage Underground Cables".

THE Council of the Institution of Electrical Engineers has appointed a special technical committee, representative of electrical engineers, medical men, and radiographers, to obtain papers on radiological and electromedical subjects, and to deal with such other matters as may be referred to it by the Council. The aim is to stimulate and foster interest in the electrical engineering aspect of radiology.

IN the autumn issue of the *Fight against Disease*, the quarterly journal of the Research Defence Society, tributes are paid to the late Lord Knutsford, who was chairman of the Society from 1908 until his death. There is also an excellent portrait. Comment is also made upon litigation concerning the Grove-Grady will, under which a sum of approximately £200,000 was to be devoted to the founding of a new antivivisection organisation ; the Court of Appeal held, however, that it was not a valid charitable gift.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A bacteriologist at the Royal Free Hospital and a lecturer in bacteriology at the School of Medicine for Women—The Warden and Secretary, School of Medicine for Women, 8 Hunter Street, W.C.1 (Jan. 8). A Massey scientific research fellow at University College, Nottingham, for research on cancer by physical and chemical methods—The Registrar, University College, Nottingham (Jan. 8). A principal of the Woolwich Polytechnic—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, S.E.18 (Jan. 23). A dean of the British Post-graduate Medical School—The Chairman of the Governing Body, British Post-graduate Medical School, New Public Offices, Whitehall, S.W.1 (Feb. 15). A professor of physics and a professor of botany at University College, Cork—The Secretary, University College, Cork. An assistant to the Editor and Secretary of the Society of Chemical Industry—The President, Society of Chemical Industry, 46 Finsbury Square, E.C.2.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Constitution of the Keratin Molecule.

As a result of a study of the action of acids on wool, it has been possible to identify one of the most important linkages in the keratin molecule. The following is an outline of the argument.

Wool fibres are easier to stretch in acid solution than in water at the isoelectric point, but when they are washed free from acid in running water, they show an almost perfect recovery of the original elastic properties.[1] Nitrous acid is similar to other acids in causing a reduction in the resistance to extension, but its effect on the fibre is incapable of being reversed by prolonged washing in running water. This peculiarity is clearly due to the irreversible conversion of amino groups into hydroxyl groups,[2] and the otherwise similar action of nitrous and other acids on wool suggests that *all* acids react primarily with the free amino groups present.

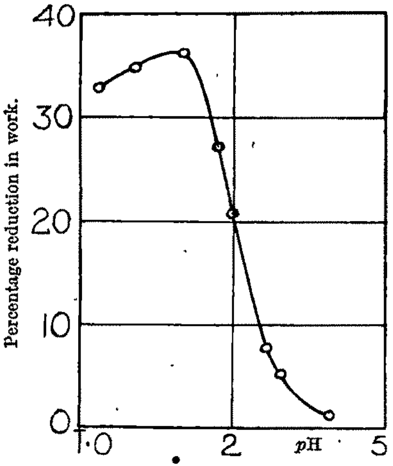

FIG. 1.

The preceding deduction may be substantiated as follows. The reduction in the work required to stretch fibres in hydrochloric acid solutions of varying *p*H has been determined in a manner precisely similar to that described in an earlier communication on sulphuric acid solutions.[3] It is clear from the results, which are reproduced in Fig. 1, that reaction between wool and hydrochloric acid is complete at about *p*H 1, just as in the case of sulphuric acid. Similarly, the removal of hydrochloric acid from solution by wool reaches completion at the same *p*H, as shown by the data of Fig. 2.* If, however, the action of acids on wool is concerned primarily with its free amino groups, then the acid adsorbed by wool at *p*H 1 should be chemically equivalent to its content of free amino nitrogen. From the curve of Fig. 2, it will be seen that 100 gm. of dry wool adsorb about 80 c.c. of *N* hydrochloric acid at *p*H 1, and the percentage of free amino nitrogen in wool must therefore be 14 × 80/1000 = 1·12 per cent. Direct determination of the amount of free amino nitrogen in the Cotswold wool used in these experiments has already given values which range from 0·94 to 1·11 per cent.[4]

The removal of hydrochloric acid from solution by wool must therefore be due to simple chemical combination with free amino groups. If further support for this view should be necessary, it is afforded by the fact that a linear relationship holds between the reduction in the work required to stretch fibres in acid solution and the corresponding amount of acid adsorbed, as shown in Fig. 3. Each molecule of hydrochloric acid combined with wool contributes a definite quantum to the total reduction in the resistance to extension observed in strongly acid solutions. It must, however, be clearly understood that precise relations of this type are not to be expected in the case of acids weaker than hydrochloric, for reasons to be discussed elsewhere.

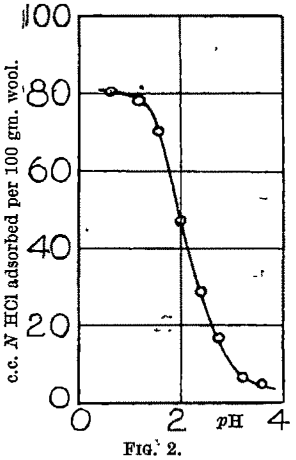

FIG. 2.

So far, it has been shown that acids react with amino groups in wool and, in so doing, make it easier to stretch. It is obvious that stretching could not be facilitated by acid were it not that the amino groups are already combined in some way to form a link which opposes extension. The most probable mode of combination is with a carboxylic acid giving a link of the type: R_1–COO–NH_3–R_2. When wool is immersed in acid solution, the carboxyl group is displaced by the external acid, the link is opened and extension of the fibre facilitated. Assuming such a link as the above to exist in wool, its position with regard to the fibre structure may be deduced as follows.

Studies of the structure of the wool fibre by the methods of physical chemistry [5, 1] and X-ray analysis [6, 7, 8] have shown conclusively that the fibre is constructed from long-chain protein molecules arranged parallel to its length. X-ray analysis indicates that these chains are simply peptide chains folded into a series of hexagons, but the precise nature of the side linkages between them has remained undetermined.[7] The suggested linkage of the type: R_1–COO–NH_3–R_2 must be one of these linkages, because wool fibres, on treatment with acid, show only a negligible change in length (which may be a contraction), whereas the increase in cross-sectional area is always considerable and may, with acids like formic acid, attain a value as high as 125 per cent.[1] Thus the linkage opened by acid must lie between the long-chain protein molecules from which the fibre is constructed.

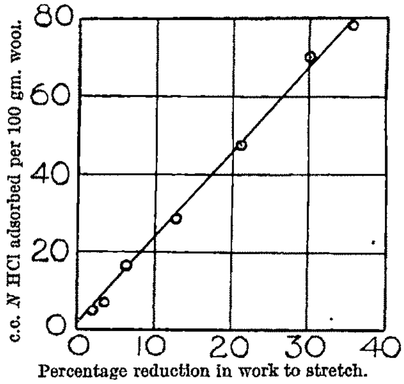

FIG. 3.

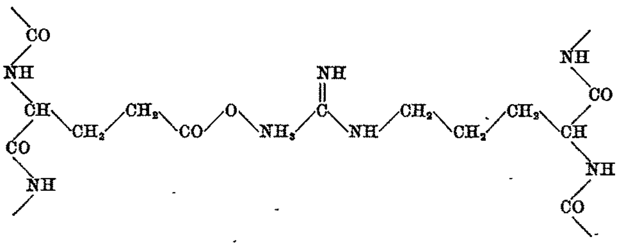
Proof that the suggested linkage really occurs in wool, and more exact details of its nature, may be obtained as follows. Such a linkage can be formed only from diamino and dicarboxylic acids. The diamino acids available for the purpose are arginine and lysine, which, according to Marston,[9] are present in wool to the extent of 10·2 per cent and 2·8 per cent respectively. If, as must be the case, one of the two amino groups of each acid forms an integral part of the long peptide chains, the arginine and lysine would together account for 1·09 per cent by weight of free amino nitrogen in wool. Thus the whole of the arginine and lysine present must be involved in the linkage under discussion. The dicarboxylic acids available for combination with arginine and lysine are glutamic and aspartic acids. In each case, one carboxyl group would form an integral part of the long peptide chains, the other being combined in the side link with the amino group of arginine or lysine.

---

* These figures are taken from a hitherto unpublished investigation carried out in conjunction with Mr. A. E. Battye in 1925. Recent research has provided an explanation of the anomalies then observed in the adsorption of different acids by wool.

Using Marston's data, the arginine and lysine are together equivalent to an amount of glutamic acid equal to 11·4 per cent by weight of the wool, and the amount present is 12·9 per cent.[10] The aspartic acid content of wool is small and of the order of 2·3 per cent. In view of the varying difficulty of estimating the different products of protein hydrolysis, the equivalence between the arginine and lysine content of wool and its glutamic and aspartic acid content is surprisingly precise. Thus the main link between the long-chain peptide molecules of wool will be a salt of glutamic acid and arginine, with the occasional replacement of glutamic acid by aspartic acid and of arginine by lysine. The precise nature of the link is given in the following formula, glutamic acid and arginine being taken as typical units :



According to this formula, the distance between the long peptide chains will be of the order of 14 × 1·25 = 17·5 A., whereas when aspartic acid and lysine form the link, the distance will be about 12 × 1·25 = 15·0 A. The corresponding spacing in the X-ray photograph of wool must therefore be of the same order as these values, or a multiple of them, but precise agreement should not be expected, because the side link may not be at right angles to the peptide chains. One of the two chief side spacings observed by Astbury[6] is, however, of the order of 27 A., almost double the calculated value. Further, according to Astbury, the reflections characterising this spacing are of the very diffuse type required by the occasional replacement of glutamic acid by aspartic acid and of arginine by lysine.

Evidence in favour of the suggested linkage is, however, not limited to calculations and coincidences of this kind. When a wool fibre is stretched, Astbury has shown that the reflections typical of the 27 A. spacing disappear, and from his model of the 'keratin complex' it is clear that the side link under discussion must rotate through an angle of at least 109° 28′.[8] Such rotation is clearly impossible unless the side linkage is opened at the $-COO-NH_3-$ group. In other words, when a wool fibre is stretched in water, work has to be done in opening the $-COO-NH_3-$ groups, the smaller resistance to extension in acid solution being due to the fact that these groups are already opened by acid before extension commences. Thus the difference between the work required to stretch fibres in, say, $N/10$ hydrochloric acid and in distilled water is a measure of the heat of formation of the $-COO-NH_3-$ linkage from free acid and base. The actual value for the reduction in the work required to stretch fibres 30 per cent of their length in $N/10$ hydrochloric acid, compared with that required in water at the isoelectric point, is $3·86 \times 10^7$ ergs, or 0·923 calorie per gram of wool. But 100 gm. of wool combine with 80 c.c. of N hydrochloric acid at pH 1, so that the reduction in the work to stretch fibres, corresponding with the adsorption of one gram molecule of hydrochloric acid, is $92·3 \times 1000/80 = 1·15 \times 10^3$ calories. This value is in close agreement with that for the neutralisation of the weak acid hydrogen cyanide by the weak base ammonia, namely, $1·3 \times 10^3$ calories per gram molecule of base.[11]

The cumulative evidence presented in this note is such as to leave no doubt that one of the linkages between the long peptide chains in the keratin molecule is a salt of glutamic acid and arginine, qualified by the fact that glutamic acid may occasionally be replaced by aspartic acid and arginine by lysine.

In conclusion, we wish to express our indebtedness to the Government Grant Committee of the Royal Society and to the Clothworkers' Company of London, for grants in aid of the present investigation.

J. B. SPEAKMAN.
MERCIA C. HIRST.
Textile Chemistry Laboratory,
The University, Leeds,
Oct. 19.

Chinese Alchemy.

IN the supplementary volume of his "Entstehung und Ausbreitung der Alchemie" (1931, p. 17), Prof. E. O. von Lippmann refers to my note on Chinese alchemy,[1] and since he appears to assume that in these matters silence gives consent (see his work, p. 40), it seems necessary to make some reply to his statements. He had adopted in the first volume of his book (1919, 449 ff.) the thesis of Berthelot that alchemy in China was transmitted through the Arabs, and this view, which is not held, so far as I am aware, by any competent authority at present, he maintains in the new volume. The sources of his information in both volumes are considerably removed from the originals, and for this reason he has probably not noticed that they are almost entirely based on the important paper by Edkins, which he refers to as 'old'. He directs attention to a review by Laufer[2] of Johnson's "Study of Chinese Alchemy" (also largely based on Edkins's paper) as in some way representing 'modern' opinion on the matter. In this review Laufer makes no contribution to the subject, merely referring to Maspero's 'critical work' on China.[3] Maspero, however, does not mention alchemy beyond a vague remark that it probably reached China from India in the third century A.D., a thesis which is not at all in agreement with Prof. Lippmann's. An Arabic origin of Chinese alchemy seems to me improbable on several grounds. In addition to those already given, I may refer to the statement of Al Nadim in the "Fihrist",[4] which shows that, even in the early period (A.D. X cent.) of the study of Arabic alchemy, an Indian or Chinese origin was considered possible. Another fact which seems to speak against an Arabic origin of Chinese alchemy is that its study was almost entirely confined to Buddhist circles, both in India and China.

A further statement made by Prof. Lippmann, to the effect that Stapleton, Husain, and Azo support an Arabic origin of Chinese alchemy, is incorrect, as will be seen by referring to the publication of these authors, or to my summary of it.[5] A similar inversion of the views of these authors appears in Prof. Lippmann's account of Indian alchemy,[6] and many such examples of lack of care in quoting authorities could be given from both his volumes. That an unfamiliarity with a foreign language might be the cause does not seem to be a satisfactory explanation, since the same course is taken with publications in German (see, for example, the reference to Hammer-Jensen's work on p. 9, and the very serious error with respect to Roger Bacon on p. 53, ref. 2).

The difficulty about quoting 'authorities' in the way adopted by Prof. Lippmann is that almost any view may be supported by a suitable choice of authority. An example in my own experience may serve to illustrate this, since an eminent authority on China referred me to a recent paper on Chinese alchemy in which it was asserted that alchemy began in China in 1100 B.C., that the Chinese had a theory of phlogiston several centuries before Becher and Stahl, and that glass was made in China in prehistoric times. Most of the publications on Chinese alchemy merely repeat what was collected by Edkins; although Wieger's great treatise on Taoism[7] gives a list of more than a hundred and fifty Chinese treatises on alchemy, not one of these has been critically examined or translated. A beginning in this study, the necessity of which was pointed out in my original notes,[1] has been made by Prof. T. L. Davis with the assistance of a native scholar, and since he has been fortunate enough to enlist sympathy in a region where I personally found none, we may expect some real additions to knowledge. The purpose of this note is mainly to indicate the doubtful value of a source of information which may be quoted as authoritative, and to the necessity of preserving a perfectly open mind on the question. New Yields from the Oldoway Bone Beds, Tanganyika Territory.

IN NATURE for Oct. 24, 1931, a letter from us was published giving the first results of our work at Oldoway in Tanganyika Territory; we should be grateful if the following additional results could be recorded:

(1) Bed No. 1, the lowest bed in the Oldoway series, has now yielded an extensive fauna which includes *Deinotherium* sp., *Hipparion* sp., and also *Elephas* (*antiqus recki* ?). The *Deinotherium* cannot be regarded as a derived fossil, since five complete teeth were found amongst a partially articulated skeleton. In Bed 1, at two different sites, we have found artefacts of a Pre-Chellean type actually with *Deinotherium*.

(2) Bed No. 2, at its base, contains tools of an early Chellean type of large size, and in its upper part, at the same horizon as the human skeleton found by Reck in 1913, tools of a more advanced Chellean type. Thus *Homo sapiens* is shown to be the contemporary, and presumably the maker, of an advanced Chellean type of culture. The fauna includes *Hipparion* and *Elephas antiqus recki*.

(3) Bed No. 3 has yielded a series of tools which may be regarded as transitional from the Chellean to the Acheulean stage of culture development.

(4) Bed No. 4, in its lower part, has yielded a big series of tools of an early Acheulean type, whilst in its higher levels we have found an old open station site which has yielded more than 500 perfect advanced Acheulean type tools. Even Bed No. 4 includes in its fauna *Elephas antiqus recki*, *Hipparion*, *Pelorovis*, *Hippopotamus gorgops*, and *Equus* sp., and we know, from the results of the material obtained by Reck in 1913, that more than fifty per cent of the species are extinct.

(5) Bed No. 5 overlies the other four beds unconformably and is separated from them by a long period of earth movement and erosion. At two sites in bed No. 5 we have found tools of an upper Kenya Aurignacian type.

(6) In view of the evidence of the fauna, and also in view of the fact that we have in beds Nos. 1 to 4 the gradual evolution from a Pre-Chellean type of culture to a developed Acheulean, we incline to the view that this part of the Oldoway series represents the lower and middle Pleistocene, a period which Leakey and Solomon have shown to be represented in Kenya by Gregory's Kamasian series.

Latency of Seedlings in some Grasses.

EXPERIMENTS at this Station have shown that when seeds of *Lolium italicum* are sown in the field together with those of certain other grasses (notably *Festuca pratensis*, *Phleum pratense*, and *Poa trivialis*), the early establishment of the latter may be considerably diminished as compared with that occurring in the absence of the rye-grass. Some months after sowing, an increase in the establishment of the same grasses is often shown. In seeking an explanation of this behaviour, a peculiar property of grass seedlings has been revealed.

Under certain conditions, when seeds of *F. pratensis*, *P. pratense*, and *P. trivialis* are sown between plants of *L. italicum*, the seedlings which result develop with extreme slowness, and after several months are no larger in size than is normally the case two weeks after germination. Such seedlings, growing in the open under conditions of low mineral nutrition and poor illumination, have been found to be remarkably persistent. The mortality in seedlings of *F. pratensis* has been after 10 months 29 per cent; in seedlings of *P. pratense*, 3 per cent after 4 months; and in those of *P. trivialis*, 4 per cent after 3 months; a high proportion of the seedlings of each species has remained alive for much longer periods.

In each case, the seedlings proved capable of normal development when transferred to a favourable environment.

There is no reason to suppose that this behaviour is peculiar to these species only of grasses, and its importance to agricultural practice is obvious. It would also seem probable that the ability of seedlings to persist for long periods in an environment unfavourable to growth and to develop normally afterwards must be an important factor in competition under feral conditions. In the colonisation of denuded areas, for example, its effect would be to increase the chances of establishment of species the seeds of which germinate slowly, and in the invasion by alien species of areas already occupied by other plants (especially when this is a consequence of the grazing, and other activities, of animals) the value to any species of this behaviour in the seedling stage would also seem clear. In this connexion it would be extremely interesting to know if a similar phenomenon is shown by the seedlings of any dicotyledonous plants.

Zeeman Effect of a Forbidden Line.

THE Zeeman effect is one of the most powerful methods of finding the causes of the occurrence of forbidden lines. The selection rules which govern it are quite different for ordinary lines, for quadripole lines, and for lines the appearance of which is due to external electric fields.

Quite recently the Zeeman effect of quadripole lines has been experimentally investigated. We have now been able to obtain the Zeeman effect of a line which shows the characteristic features of a line due to the random electric fields of the discharge, for example, the components with $\Delta m = 0$ are observable in the transverse direction as σ- and π-components.

The mercury line $6\,{}^3P_2 - 7\,{}^3P_2$ $\lambda = 3680$ A., which is forbidden by the selection rule for the azimuthal quantum number, was investigated in a magnetic field of about 12,000 gauss. As light source an arc in vacuum was used.

If this line was due to quadripole radiation, its Zeeman pattern would have been of the type $\frac{(3)\ 6}{2}$, with all the components of equal intensity as shown in Fig. 1. Assuming an electric field distributed at random, the type can be calculated by means of the Schrödinger perturbation theory (we are indebted to Dr. E. Majorana for this calculation), and one obtains the pattern of Fig. 2 of the type $\frac{(0)\ (3)\ 0\ 3\ 6}{2}$. (The numbers in the figure denote the calculated intensities of the components.)

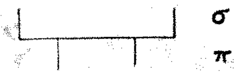

FIG. 1.

Moreover, we should expect that the line would be rather diffuse owing to the rapid variability of the electric fields, due to the ions which are present in the discharge and to the Stark effect shift.

What we actually observed without field was a rather diffuse line. In the magnetic field the line showed little alteration, but became a little broader, especially in π-polarisation.

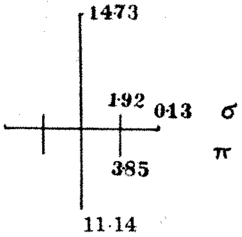

FIG. 2.

The diffusion was real because the Zeeman pattern of other lines on the same plate, for example, $\lambda = 3662{\cdot}88$ $6\,{}^3P_2 - 6\,{}^3D_1$ of mercury, Zeeman pattern $\frac{(0)\ (2)\ 1\ 3\ 5}{2}$, were resolved. Anyhow, from our photographs we conclude that the Zeeman pattern was a centred one both in π- and σ-polarisation. If the Zeeman type had been as in Fig. 1, corresponding to quadripole radiation, we should undoubtedly have seen a non-centred type and probably should have resolved components separated by 3 and 6 normal units, even with a line originally so diffuse, if they had occurred.

Moreover, the broadening of the π-components is a confirmation of our interpretation, because, as shown in Fig. 2, the lateral components in π-polarisation are in the same position as, but double the intensity of, those in σ-polarisation.

We hope to repeat the experiment with a stronger magnetic field.

We are indebted to Prof. P. Zeeman for his interest and advice in connexion with this investigation.

Neon-Helium Bands.

IN the course of some experiments on the spectrum of the negative glow, some bands near 4000 A. were observed in the negative glow of neon-helium mixtures. The definite experiments were carried out in the following way.

Two glow lamps (nickel plate cathode, ring anode) were joined by a glass tube; in the tube was a small glass bulb which separated the gases from another, and the bulb could be shattered by a small iron ball. One glow lamp was filled (after degassing) with neon and the other with helium, both at a pressure of 6 mm. of mercury. Spectrograms were taken of the two negative glows with a small glass spectrograph, Fig. 1.

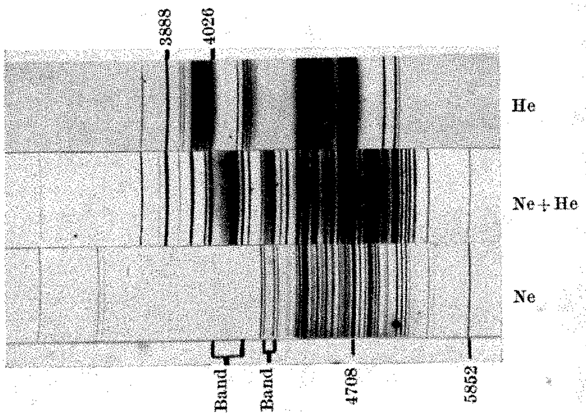

FIG. 1.

In the neon glow the neon arc- and spark-lines were observed, in the helium glow the helium lines and the He_2-bands were present. Then the small glass bulb was shattered, so that the gases were mixed and a new spectrogram was taken. The He_2-bands had now disappeared, but besides the neon and helium lines two bands were observed, the stronger one between the helium lines 4026 and 4121, the other one between 4219 and 4276. Although the bands could not be resolved, it seems very improbable that they would coincide with He_2-bands. The most probable explanation seems that the bands are to be attributed to a compound of neon and helium, such as Ne-He.

Prof. Coster in Groningen was so kind as to take some spectrograms of these bands with a grating; on some plates the bands were partly resolved, but the intensity was too low to photograph the lines with greater dispersion. To obtain a greater intensity I looked for these bands in a direct current positive column in a neon-helium mixture, but I did not obtain the bands.[1] Maybe this can be attributed to the fact that in the negative glow a great velocity range of electrons is present, while in the positive column studied the electronic velocity was too low. In the negative glow the bands disappeared when 10 per cent argon was added to the neon-helium mixture. The bands did not change when the lamp was cooled with liquid air.

The Study of Specific Combination in Immunity Reactions.

IT can scarcely be denied that up to the present the study of immunity reactions has been especially difficult owing to current theories being most vague and conflicting. As a result much of the work done has shown a lack of method and definite line of attack. It seemed to us that if a reaction, in which at any rate one of the reacting substances was a definite chemical compound, could be studied, this would form a sound basis for further investigation. This we have attempted to do.

The work of Landsteiner and others [1] affords strong evidence that in certain precipitin reactions the first stage of the reaction is the combination of antibody with definite chemical groups in the antigen. This work has shown (1) that the sera of rabbits immunised with a protein to which one of various chemical groups has been attached will give a precipitate with any protein to which this group has been attached, and (2) the simple substances (haptenes) containing the active chemical group, although they do not give a precipitate with the serum, when added in excess inhibit the formation of a precipitate by serum and protein containing the active group. Presumably there are two stages in such a precipitin reaction: first a specific combination of chemical groups with antibody, and second a molecular rearrangement, leading to precipitation, which does not take place unless these groups are attached to protein. This suggests a method of simplifying the study of immunity reactions by confining the investigation to the first stage and using as one of the reacting substances a haptene, that is, a chemical compound of known composition.

Since the haptenes will pass through a collodion membrane and the antibodies will not, it is possible to measure the concentration of free haptene in a mixture of haptene and antibody by dialysis. Non-static methods such as the ultracentrifuge and ultrafilter would not be sound, as the amount of haptene bound by antibody may vary with the antibody concentration, and water probably passes through a membrane faster than the haptenes. Using a small dialysing apparatus so designed that the concentration of haptene in the antibody-free fluid could be measured photometrically without its removal, we have been able to demonstrate the specific combination of antibody with haptene. We used *p*-aminobenzene arsinic acid (atoxyl) as the active group; this was diazotised and coupled with horse serum-pseudoglobulin to form the antigen, and with tyrosin to form the haptene.

Using a solution of haptene approximately $M/25,000$, the ratio of haptene bound by globulin prepared from immune sera to that remaining free was approximately 2/1. We used, as control, globulin from normal rabbit serum and globulin from immune serum from which the antibody had been removed by precipitation with excess of antigen; with these the ratio of bound to free haptene was approximately 1/6. We were not dealing simply with an increased power of adsorbing azo-dyes, since *o*-carboxybenzene-azo-dimethylaniline (methyl red) was not adsorbed any more by immune serum globulins than by normal globulin. On the other hand, atoxyl diazotised and coupled with *p*-cresol behaved in the same way as the tyrosin compound. This direct method therefore confirmed Landsteiner's supposition that haptenes combine specifically with antibodies.

We hope so to improve this method as to obtain accurate measurements of the amount combined under varying conditions. Such specific combinations may be involved in many biological processes and certainly are essential to enzyme action. Hitherto the methods of their study have been limited. In the case of enzymes direct methods have not been suitable for quantitative work and kinetic methods involve considerable assumptions.

Evidence has accumulated of recent years that antibodies are modified serum globulins. It may be hoped that, with increasing knowledge of the nature of the combination between haptenes and antibodies, it will be possible to correlate this process and the further stages of immunity reactions with theories of protein structure such as have been outlined in recent letters to NATURE.[2]

Structure of the Azides.

WE have just seen Dr. Sutton's communication on the "Structure of the Azides, from their Electric Dipole Moments".[1] We also have measured the dipole moments of phenylazide, *p*-chlorphenylazide, and *p*-bromphenylazide and found the values 1·55, 0·47, and 0·64 × 10^{-18} e.s.u., respectively, in good agreement with Dr. Sutton's data. We believe that the moments for the two halogeno-compounds are really zero or very small, because we must neglect their atomic polarisation. The moment of the molecule is, therefore, the vectorial sum of the moments of the substituents.

Dr. Sutton considers his measurements as evidence in favour of the cyclic structure of the azide-group , because in that formula the moment-vector coincides with the R – N linking, and, indeed, the parachor measurements of Lindemann and Thiele [2] are in harmony with his conclusion. But we cannot agree with this. A short time ago, L. Pauling [3] determined exactly the crystal structure of potassium azide. The data given by him show that the three nitrogen atoms lie on a straight line.

It seems, therefore, possible that any 'open-chained' formula for the azide-group may hold true. We can accept that the argument of Dr. Sutton in terms of the octet theory for ruling out the classical formula $R - N = N \equiv N$—the central nitrogen atom would have a shared decet—is not decisive, because the octet rule of valency electrons seems not to be a comprehensive law (compare the existence of sulphur hexafluoride, etc.). Probably also the formula $R - N = N \xrightarrow{} N$ is valid because the angles between the links in an azide molecule are very uncertain. The dipole measurements by no means contradict the assumption that the three nitrogen atoms lie on a straight line; the data given by Pauling seem to prove it.

With regard to the very interesting work of Lindemann and Thiele, it seems that the parachor measurements do not give a definitive structural proof,[4] because in the series of the aliphatic diazo-compounds very closely related to the azides there is a discrepancy between the parachor measurements and the chemical evidence. The former evidence [5] is in favour of the cyclic structure, but such a structure is unable to account for the existence of optically active diazo-compounds.[6] Also, the assumption of an equilibrium between the cyclic and the open-chained molecules is not in harmony with the observed optical properties of the compounds cited.[7]

A Two-Dimensional Space Lattice?

AFTER reading the letter from Dr. R. C. Menzies in NATURE of Nov. 28, I wrote to him stating what I believe to be the cause of the orientation of the growing crystals at the liquid surface, and it is at his suggestion (letter dated Nov. 30) that I submit this note for publication.

The explanation probably lies in the convection currents set up by the growing crystals. When a crystal is floating by surface tension forces at the surface of the solution, some of the molecules of solute in the neighbourhood will be deposited on the crystal and this will decrease the density of the solution in the immediate vicinity. The crystals are thus centres of local rising currents and will therefore mutually repel each other, since the currents must spread out sideways on reaching the liquid surface. Crystals of the same size will exert the same lateral forces and must take up the close-packed hexagonal arrangement shown in the photograph. Larger crystals may be expected to exert greater forces than smaller ones, so that a swarm of large crystals will have a greater spacing than a swarm of smaller crystals when both swarms are floating in the same liquid surface; this is very apparent in a second photograph sent to me by Dr. Menzies. The effect may break up owing to (*a*) the sinking of the crystals, (*b*) the crystals growing sufficiently large to touch and unite, or (*c*) as Dr. Menzies has pointed out to me, the reaching of equilibrium between crystals and solution, when the surface currents must cease.

I have noticed the same structure in the crystallisation of a number of organic compounds, though in a much less perfect form. Substances which readily separate from hot solution in compact crystals usually give the lattice effect to a greater or lesser degree, though failing spontaneous crystallisation it is necessary to drop a little of the finely powdered substance on the surface. The phenomenon is shown somewhat feebly by 4-nitropyrogallol 1:2-dimethyl ether crystallising from alcohol, and by 4-iodopyrogallol trimethyl ether separating from light petroleum. Undoubtedly the spontaneous crystallisation and great density of the thallium derivative are responsible for the unique perfection of the case described by Dr. Menzies.

The Tertiary Wall of Wood Fibres.

IN addition to the primary and secondary walls of the fibres of the secondary xylem of angiosperms, a third inner wall is not infrequently present. This layer is commonly known as the tertiary wall, and so far little is known of its exact nature or function. The distribution of the tertiary fibre walls in trees suggests, however, that their formation is influenced by environmental conditions, and may therefore admit of a certain amount of control.

A recent study of the occurrence of tertiary fibre walls in the wood of elm [1] led to the conclusion that these layers add to the specific gravity of wood without contributing a proportional increase to its mechanical strength. A study of the moisture relations of wood the fibres of which contain tertiary walls was undertaken to examine the commonly quoted statement that these structures influence the hygroscopicity of wood and "prevent undue shrinking and swelling".[2] Fifteen carefully matched pairs of wood specimens from several trees of *Robinia Pseudacacia* L. and of *Ulmus campestris* L. were selected, so that tertiary fibre walls were present in one member of each pair and absent from the other. Comparison of these samples revealed no difference in behaviour that could be attributed to the presence of tertiary fibre walls, either in the total shrinkage of the wood from the green to the oven-dry condition or within any shorter intermediate range of moisture content. It is true that the shrinkage of the wood of *Robinia Pseudacacia* is somewhat less than might be expected from its structure, but the reason must be sought in other features than the presence of tertiary fibre walls.

Turbulence in a River.

IN the river Cam, in its normal state, the conditions correspond to an eddy viscosity of the order of 1000 cm.^{2}/sec. It therefore seemed remarkable that in my work on the formation of surface waves by wind [1] the conditions for formation were the same in the river as on a pond.

It occurred to me that the uppermost layer in the river might actually be non-turbulent; and when this possibility was tested by dropping ink into the river it was verified. The drops spread out merely as in still water until they reached a depth of 10 cm. or so and were then torn apart by eddies.

It appears, therefore, that the stabilising influence of gravity prevents eddy motion from reaching the free surface. The formation of waves produced by a light wind, with lengths of 8-10 cm., is therefore controlled by ordinary viscosity and not by turbulence.

Research Items.

Ancient Egyptian Sealings.—During the seasons 1928–29 and 1929–30 the Harvard-Boston Expedition excavated the ancient Egyptian fortress on Uronarti (Geziret-ib-Melek). In addition, the ground south of the fort was examined, resulting in the discovery of a few graves and a large unfortified palace or dwelling-house. The fort was built in the twelfth dynasty, but abandoned as a military post before the end of the thirteenth dynasty. In the eighteenth dynasty the cult of Sesostris, the founder, was re-established and two temples built or reconstructed, the fort being occupied by the priests. An account of the results by Dr. G. A. Reisner is given in *Sudan Notes and Records*, vol. 14, pt. 1. The objects found were of no great importance, except for a large collection of sealings in mud or clay, numbering nearly five thousand. Of these, the official and the private sealings were about equal in number. Not only do these provide a large variety of designs, but they also add very considerably to our knowledge of the methods of using the seal. The sealings are of various forms. The letter seal is of firm black clay, and bears the papyrus imprint on its reverse. The funnel and double funnel sealings have a hole or holes arising from the base, and show prints of string passing two or more times around the hole. They were evidently used for sealing bags of rations and other supplies for the garrison. The parcel seal is of ordinary mud and circular in form, bearing the mark of tied string on the under side. The box seal and door seal are chiefly in slot form. The key-hole seal was forced into a hole like a key-hole. The sample seal is a single impression on a pat of mud, and has not been attached to anything. It was probably kept for comparison with the sealing of official dispatches. The sealings are usually covered with impressions of the same seal; but in a large number of cases the official seal has been over-stamped with a private seal, probably that of the officer using the official seal. It seems possible that there was a system of registration of seals, similar to that now employed in modern Egypt, to prevent fraud.

Skulls of the Pueblo and related Indian Races.—The Pueblo Indians, once inhabiting America from Texas to Arizona and from Colorado to northern Mexico, form one of the largest and most interesting of the aboriginal American groups. They are a sedentary, mainly agricultural, and peaceful people, but they have the obnoxious habit of so compressing and deforming the bones of the forehead that the craniologist stands helpless before them. However, by selecting skulls where the deformations were of minor grade, Dr. Aleš Hrdlička has been able to publish an informative report and analysis of 645 crania (*Proc. U.S. Nat. Mus.*, vol. 78, art. 2, 1931). He reaches the conclusion that the Pueblos are not a homogeneous group, but contain two distinct strains, one substantially dolichoid, the other fairly strongly brachycranic. Brain capacity and hence size of brain are relatively small, and though this may partly be attributed to the moderate stature of the people, it indicates a somewhat weakened group. As to affinities, unexpected light is shed by the skulls. The Pueblos differ substantially from their neighbours to the north-west and west, but they approach very significantly on one hand the Algonkins, and on the other hand the Gulf types of farther east. The low-vaulted Apache and related Indians now settled in the Pueblo region stand apart from the high-vaulted brachyoid Pueblos.

Distribution of Herring and Plankton.—It is of obvious value if a correlation can be shown between the abundance of herring in any area and that of their food. In *Fishery Investigations*, Ser. 2, vol. 12, No. 38; 1931 (London: H.M. Stationery Office), Mr. R. E. Savage reports on the relation between the feeding of the herring off the east coast of England and the plankton of the surrounding waters. Much information on the biology of the herring is contained in this report, which covers the Lowestoft spring fishery, the Shields summer fishery, the Yorkshire coast fishery, and the Lowestoft autumn fishery. The appetites of the herring show a diminution from May onwards through the summer, and by the autumn fishery they have practically ceased feeding. The most important feeding ground is in the Shields area, and here we have evidence of a correlation between the amount of available food and the size of the catches for the years 1922–23 and 1926. An interesting calculation is made that in order to provide all the herring landed at the English east coast seaports during 1926 with one 'average' meal, it would require three hundred tons of plankton. Useful observations are also given on the vertical distribution of various species of plankton animals. Comparison of plankton catches and stomach contents of the fish showed that the herring fed on the most abundant species in the plankton at the time, and the author is of the opinion that larger animals such as schizopods and post-larval sand-eels are definitely selected and captured, while there is a discriminate mass selection of the smaller species.

Evolution of Dominance.—Dr. R. A. Fisher has brought together in a convenient form, in *Biological Reviews*, vol. 6, No. 4, October 1931, the several groups of facts of observation upon which his theory of the evolutionary modification of dominance is based. The theory itself is the outcome of the view that the effects of Mendelian factors are largely susceptible of modification through interaction with other factors in the germinal complex. The heterozygote, in particular, since it contains both of two alternative genes, may be expected to be particularly susceptible of modification. It is shown that, from this point of view, the deleterious modifications occurring commonly in Nature and the fancy novelties favoured by man in domesticated animals and plants may both be expected to be recessive, whilst variant forms of polymorphic species should generally be dominant. The anomalous case of the domestic fowl is examined, in which a number of characters behave as dominant in crosses with the presumed ancestor, *Gallus gallus*, and the conclusion is reached that the situation here can be explained by the early history of domestication of these species. This theory asks for a reconsideration of the effect of selective action upon characteristics of very minor importance in the organism, upon, in fact, the type of difference between species which has made some students of evolution regard natural selection as a quite inadequate instrument in species production. Dr. Fisher's theory, in numerous directions, suggests further genetical experiments, often involving extensive breeding experiments with native wild populations of the organism.

Humidity Control and Entomological Problems.—In the *Bulletin of Entomological Research*, vol. 22, September 1931, Dr. P. A. Buxton contributes a short practical article on the above subject. Most of the published work bearing upon the influence of humidity on phases of insect life is in terms of relative humidity at different temperatures. We require fuller investigation as to the scale which is most appropriate for such lines of inquiry. The adoption of a constant saturation deficiency as the index may perhaps prove to be a better criterion, but the whole subject is one which has been largely neglected. Dr. Buxton discusses the several scales by means of which water vapour in the atmosphere may be measured—for example, absolute humidity, relative humidity, and saturation deficiency —and then proceeds to describe various methods for the direct measurement of humidity. These include wet and dry bulb thermometer, the use of hygroscopic substances, dew-point determination, and the working of chemical hygrometers. In dealing with methods of controlling humidity, the use of supersaturated salt solutions, sulphuric acid, and aqueous solutions of potassium hydroxide are dealt with critically, their advantages or disadvantages, as the case may be, being referred to briefly. Appropriate apparatus wherein controlled experiments can be carried out also comes in for some mention. The use of desiccators is favoured by Dr. Buxton, who, it may be added, further takes into account the needs when a current of humidified air is desirable. The paper is one likely to be useful to those biological workers who are not familiar with experiments requiring control of humidity (see also NATURE, Nov. 14, p. 837).

Liming and Fertility.—Although liming or chalking is one of the oldest operations in British agriculture, it is now realised that much land in England is less productive than it might be owing to the neglect of this practice during the past fifty years. Increase in costs and the introduction of artificial manures have probably largely contributed to this falling off in the use of lime, but owing to the heavy dressings originally applied, considerable time has elapsed before the soil has shown signs of losing its fertility. In view of the many failures of crops which can be attributed to a lack of lime, the Ministry of Agriculture has issued an illustrated bulletin (No. 35), entitled "The Use of Lime in Agriculture" (London: H.M. Stationery Office; 6d.), which should prove of real practical help to the farmer. The subject is introduced by a survey of the chief functions of lime. An account of the causes and rate of loss of lime from the soil follows, and definite symptoms of both grass and arable land deficient in lime are described. Remedial measures are considered in detail, the comparative values of the various forms of lime and chalk on the market, such as free and slaked lime, carbonate of lime, waste lime products, and lime rich in magnesia being fully discussed. Definite information as to the best quantity to apply is less simple to provide since conditions are so diverse, but advice on general lines is given, and if in any doubt the farmer is recommended to communicate with his county agricultural organiser.

Cross-Pollination in Cotton.—A study of the frequency of natural crossing between adjacent varieties of cotton, for which de Vries coined the useful term 'vicinism', has been made by Dr. M. A. Fikry (*Tech. Bull.* No. 18, Roy. Agric. Soc. Egypt). He planted strips of Red Leaf Acala cotton, which is homozygous for a dominant red leaf factor, in a field of Maarad cotton having green leaves. The plants are visited by insects, especially the honey bee and another bee of the genus *Nomia*, but wind is negligible as a factor in crossing. By making two pickings of Maarad seeds from successive ridges at increasing distances from the Acala and determining the percentage of red seedlings in each case, the conclusion was reached that 4 per cent of the seed from each plant in a cotton-field is crossed, that is, there is 96 per cent of self-fertilisation. A gradient of pollination, beginning with the source of pollen, gradually falls to zero at about forty metres, which is the maximum range to which pollen was transmitted. The amount of vicinism will no doubt vary, depending especially on the frequency of insects and the distance between the plants, but the figures obtained are a measure of the precautions necessary to maintain purity in a cotton crop.

Seeds and Seedlings of Sâl.—Some investigations are being carried out by Mr. H. G. Champion and Mr. B. D. Pant on the seed and seedlings of the Sâl (*Shorea robusta*), one of the timbers of chief commercial importance in more than one province of India (*Ind. For. Rec.* (Silv. Series), vol. 16, pt. 5; 1931). One of the conclusions reached with reference to the seed is that no relation has yet been demonstrated between the average size of the seed from a given tree and the vitality and vigour of the resultant seed crop. This is contrary to an opinion expressed in 1928. The authors consider, however, that "since the bigger the seed the better it is, one would expect the average for trees with relatively big seed to give higher average values for plant per cent and seedling height". There is a remarkably wide range in size of the seed from 0·308 in. to 0·561 in. The root system of seedlings is described in relation to soil factors, etc., and seedling types in line sowings are differentiated and their relative development studied. The interesting fact is recorded that "seedlings with several equal shoots develop nearly as well as those with a single or dominant shoot, and the presence of small shoots increases the growth of a dominant shoot". Burning back seedlings three seasons old makes no significant difference to the shoot height reached the following season. Experiences with the growth of cover or shelter crops between the lines of young sâl seedlings, notably with the crop *Tephrosia candida*, with which remarkable results have been attained in some parts of India, are described.

Tertiary Foraminifera.—A memoir by Dr. W. A. Macfadyen on "Miocene Foraminifera from the Clysmic Area of Egypt and Sinai" (*Egypt. Geol. Survey*, Cairo, 1931; pp. 149, pls. 4, map) deals mainly with the Foraminifera from the marls of the Clysmic (or Greater Gulf of Suez) area of Egypt and Sinai, but is preceded by an account of the stratigraphy and correlation of the deposits. Descriptions are given of nine carefully measured sections taken at different parts of the region, and the beds are regarded as of Burdigalian, Schlier, and Helvetian ages, with perhaps some representative of the Tortonian. The succession is compared with the Miocene series of Vienna, Transylvania, Malta, and Cyprus. The greater development of the foraminiferal marls in the central part of the area is taken to indicate that the faulted Clysmic trough was already in existence in Schlier times. The Clysmic area formed an arm of the Mediterranean in Miocene times and was not connected with the Indian Ocean until the Pliocene period; consequently the majority of the 185 species and varieties of Foraminifera recorded by Dr. Macfadyen are known to occur in the Tertiary or recent faunas of the Mediterranean region. Dr. J. A. Cushman and J. D. Barksdale (*Contrib. Depart. Geol. Stanford Univ.*, 1, 2, 1930; pp. 55-73, pls. 11, 12) describe the Foraminifera of the Martinez Eocene of California, and conclude that that formation is of the age of the Claiborne beds of the Gulf Coastal plain of the United States and Mexico.

Illumination in Factories.—The question of the best direction and intensity of the illumination of the work in factories in order to improve the efficiency of human labour and effect economy in the cost of production has led to the formation in Germany of a

Board to carry out experiments on the subject. A report on the work done in connexion with weaving, by Drs. N. Goldstern and F. Putnoky, has been translated into English and appears in the November issue of the *Journal of the Franklin Institute*. The woollen cloth being woven was illuminated directly by lamps in enamel reflectors, indirectly by lamps sending their light to the ceiling, and by a side light introduced to give shadows of the fibres, and the intensity of the illumination of each type could be changed. Each increase of illumination produced an increased output which was greater for dark than for light material. With the costs of electric light and labour in Germany, the most economical illumination is 60-70 foot candles, which secures a net gain of 6 per cent for dark and 4 per cent for light materials. With the American costs of light and labour the net gain would probably be greater.

Formation of a Spark.—The second October number of the *Physical Review* contains an account by F. G. Dunnington of an investigation of the initial stages in the formation of a spark. The method used was that of the so-called electro-optical shutter, in which the electric impulse of the spark is applied at a variable time of less than a microsecond later to the electrodes of a Kerr cell full of nitrobenzene. This becomes almost instantaneously doubly refracting, and allows the stage of growth of the spark to be seen or photographed through a polarising system. The way in which the spark-gap collapses varies. The bright conducting filaments, which follow the initial dark discharge, may appear either at the cathode or both at the cathode and in the gas. Effects such as the latter indicate that space-charges are present, and with this criterion it is found that they become more important as the number of molecules between the sparking electrodes is increased. Other interesting observations were made, such as the occasional development of a single bright filament into a bundle, and an attempt is now being made to follow the growth of the spark spectroscopically.

Flame Temperatures.—Measurements of the flame temperatures of binary mixtures of gases in admixture with air are described by Jones, Lewis, and Seaman in the November *Journal of the American Chemical Society*. The addition of oxygen to methane raises the maximum flame temperature with air by about five per cent with 20 oxygen to 80 methane. Addition of hydrogen to methane raises the flame temperature only slightly up to about eighty per cent of hydrogen, after which it increases rather rapidly. The maximum flame temperatures of mixtures of methane and acetylene indicate that the addition of small amounts of acetylene to pure methane causes a considerable increase in flame temperature. The temperatures from pure methane to 20 methane + 80 acetylene lie practically on a straight line when plotted against composition. It was not possible to determine the flame temperature of pure acetylene mixed with air, but a slight extrapolation gave the maximum of 2325° C. The highest temperature was in all cases reached with mixtures slightly on the rich side, that is, having an insufficient amount of oxygen present to consume all the combustible substances. This is in agreement with results with single hydrocarbon gases and air. Calculations of the flame temperatures gave satisfactory results.

Astronomical Topics.

Sigma Scorpii.—*Popular Astronomy* for November contains a note by Mr. B. H. Dawson on an occultation of this star that he observed at La Plata on July 25. The disappearance was in two sharp steps, at intervals of less than half a second. More than half the light was cut off at the first step. Señor Dartayet made identical notes, using another telescope 50 metres distant. The note recalls similar observations made during occultations of the same star on March 12, 1860 (Cape), and April 10, 1917 (Washington). Mr. Dawson points out that a separation of the pair by about a tenth of a second of arc is indicated. This is too large for the spectroscopic system, which has a period of 33 days. M. Henroteau had already suggested the presence of another component, with a period of about twelve years; the phenomena noted during occultations support this suggestion.

The Variable Star AK Herculis.—Reprint No. 11 of the publications of Warsaw Observatory contains a careful study of this interesting variable by J. Wasiutynski. The variability was discovered in 1917 by J. H. Metcalf, the period being at first given as $0{\cdot}210760^{\mathrm{d}}$; but it was found later that the star is of the β Lyræ type, and that the complete period is twice as long. The extreme range of light is half a magnitude, from 8·2 to 8·7; the two maxima are nearly equal, but at the secondary minimum the magnitude is 8·6. There is continual variation of light, so it is concluded that it does not arise wholly from eclipses; the stars are assumed to be elliptical in outline; the value 0·12 is, somewhat doubtfully, assigned to the ellipticity. The relative orbit also appears to be elliptical, but the article concludes that it is difficult to explain all the features of the light curve without assuming that a portion of the light-variation is physical.

Report of the Paris Observatory for 1930.—This report records a large amount of useful work in many departments of astronomy. Perhaps the most epoch-making is M. Lyot's observation of the corona without an eclipse, from the station on the Pic du Midi, with the aid of a polarimeter; the streamers could be traced to a height of 6′ above the limb. The two brightest lines in the coronal spectrum, at 5303 and 6374, were also seen and photographed. A new catalogue of 10,656 stars in the zone from +16° to +24° was published; the observations had been made between 1899 and 1912.

The sheets of the "Carte du Ciel" are being published at the rate of five per month; it is hoped that they will be completed within a year. Proper motions are being deduced by comparison with the plates taken by the brothers Henry in the last century. The last volume of the astrographic catalogue has gone to press. A catalogue is also being prepared of all the stars on the plates down to magnitude 10, giving right ascensions and declinations.

Measures were made of the positions of faint stars near Pluto suitable for use as comparison stars. Studies of the orbit of Pluto were made by MM. Mineur and Barbier. M. Baldet observed it visually with the Meudon equatorial, concluding that its diameter did not exceed 0·2″; he observed the nucleus of the comet 1930 *d* (Schwassmann-Wachmann) with the same instrument when it was within five million miles of the earth, and deduced that its diameter was of the order of 400 metres.

Daily observations of the sun are made with the spectroheliograph; the results are sent to the national meteorological office and transmitted by wireless throughout France. There is also a record of much optical and chemical research in the astrophysical laboratory.

Constitution of the Alloys of Silver and Mercury.

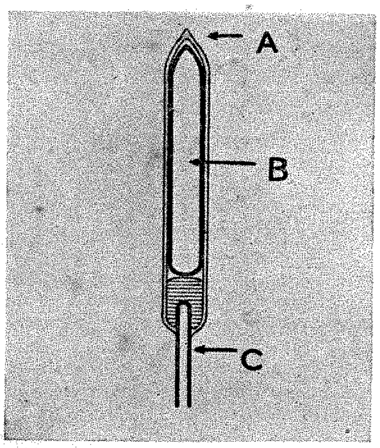

Fig. 1.

THE physical characteristics of silver and mercury place formidable experimental difficulties in the way of any attempt to apply to this system of alloys the ordinary methods of physical metallurgy. At the melting point of silver the vapour pressure of mercury is about 250 atmospheres, and in overcoming the difficulties involved great credit is due to Dr. A. J. Murphy, who, in a paper read before the Institute of Metals on Sept. 15, has investigated this thermal equilibrium diagram.

In order to obtain the necessary heating and cooling curves, the metals, in a high state of purity, and, so far as the silver was concerned, in a very fine state of division, were placed in the fused silica vessel *A* (Fig. 1), which at this stage was open. Into the tube *C* the thermo-couple wires of chromel and alumel were introduced. It was not possible to seal off the tube *A* at a distance less than 3 in. from the amalgam if undue heating were to be avoided, and to reduce the dead space that this entailed the closed silica tube *B* was introduced. The outer silica tube was finally filled with hydrogen and sealed.

With most of the alloys it was necessary to apply a high pressure to the outer walls of *A* to prevent explosion. For this purpose it was enclosed in a seamless steel bomb, fitted at both ends with massive caps which screwed down on to copper-asbestos washers. The upper cap was provided with an inlet through which gas was passed at a pressure of 120 atmospheres. An internal electric furnace circuit was then closed and heating proceeded. No variation of the gas pressure was made during the observations owing to its liability to give rise to troublesome thermal effects.

The diagram deduced is shown in Fig. 2. The α phase consists of a solid solution of the two metals. On heating to 276° C., the β phase dissociates into α and liquid, whilst the γ phase similarly dissociates into β and liquid at 127° C. Although the exact nature of the α and β phases has not been determined, formulæ of the type Ag_4Hg_3 or Ag_5Hg_4 would satisfy the observations relating to the composition of the β phase, and Ag_3Hg_4 or Ag_4Hg_5 for the γ phase.

Although in general the vapour phase is neglected in dealing with most metallic systems, this can no longer be done in that under investigation without further consideration, since both the nature and the composition of the phases might be affected by the considerable pressure under which they were formed. It is of general interest, therefore, that the author shows that the actual phases present are independent of the pressure, and that, from an application of the Clapeyron equation, the temperatures at which transformations occur are not appreciably affected.

Figs. 1 and 2 are from Dr. Murphy's paper, by courtesy of the Institute of Metals. F. C. T.

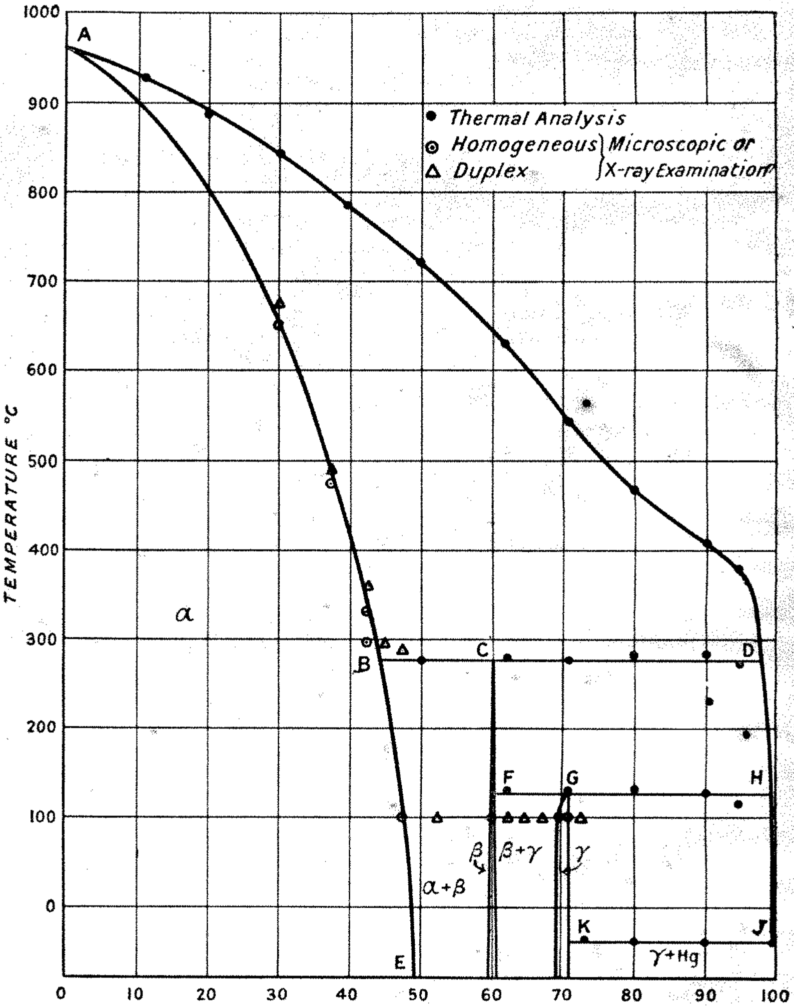

Fig. 2.—Equilibrium diagram of silver and mercury.

International Standards of Lighting.

A BRIEF summary of the chief conclusions arrived at during the session of the International Commission on Illumination (held in Cambridge on Sept. 13–19) was included in an article on the International Illumination Congress which appeared in Nature of Oct. 10, p. 642. A detailed account of the resolutions has now been issued. The series is a formidable one. There are more than seventy separate resolutions or recommendations. Of fundamental importance is the announcement that in future the Comité International des Poids et Mesures will include photometric standards within its scope. A select committee is accordingly to be formed by the International Commission on Illumination to handle this matter and co-operate with the Comité International. Other resolutions fall under the following heads: definitions; automobile headlights; factory and school lighting; street lighting; coloured signal glasses; traffic control signs; diffusing materials; test plates; photometric precision; daylight illumination; glare; colorimetry; aviation lighting; lighting education; vocabulary; heterochromatic photometry; light flux distribution, and applied lighting practice.

Under "Definition" the use of the symbol *n* for refractive index is approved, and likewise the use of c.g.s. units in official publications of the International Commission on Illumination. Authors are requested to express values (in brackets) in c.g.s units as well as in their national units. In connexion with factory and school lighting no change in the minima included in the International Commission of Illumination Code (Geneva) is made. Recommendations relate mainly to educational effort. In order to facilitate international comparisons of street lighting installations it is suggested that (*a*) a complete description of the luminaire, with its consumption of gas or electricity, (*b*) the spacing of luminaires, their height and transverse position, and (*c*) the average illumination and minimum illumination, should be given. The nominal range of a beam of an automobile headlight is specified as the distance at which an illumination of 1 lux is produced in a vertical plane. Cars driven at speeds exceeding 30 km. an hour should be furnished with (i) a driving beam (for use on the open road) and (ii) a passing beam (for use when meeting other vehicles). The intensity and lateral spread of driving beams are defined. 'Transmittance' is approved in place of 'transmission' of coloured signal glasses and lenses. The use of red at left or top, amber in centre, and green at right or bottom for traffic control signs is approved, and it is recommended that the lens diameter shall not be less than 8 in., and the lamp wattage not less than 60. Information is to be collected on the influence of traffic signs in diminishing accidents and facilitating traffic.

There were numerous conclusions in regard to diffusing materials, test plates, and photometric precision, of special interest being the statement that visual measurements are most accurate with illuminations on the photometer screen between 5 and 20 lux. Under these conditions and with no colour difference a mean error of 0·25 per cent is practicable. In commercial work an error of 3 per cent is considered usual. In connexion with daylight illumination the use of 'contour lines of constant daylight factor' is recommended. At all parts of interiors where the daylight factor at table height is less than 0·2 per cent, the daylight is regarded as definitely inadequate for work involving visual discrimination over reasonable periods of time and comparable with ordinary writing. It is proposed to set up a technical committee to study 'artificial daylight' and if possible prepare agreed forms of specifications for lighting units intended to imitate daylight. Further investigations on the sensation of discomfort associated with the presence of bright sources in the field and on the time variations of glare effects are proposed. There were a series of six resolutions bearing on standard procedure in colorimetry.

In connexion with aviation lighting there were no fewer than fourteen definitions or recommendations. The nature and position of obstruction lights, boundary lights, and airport and airway beacons were indicated. The figure of 0·2 candle at 1 km. was adopted as the requisite minimum for visibility under laboratory conditions, and experiments on the corresponding value appropriate to flying conditions are contemplated. Other recommendations dealt with the details of navigation lights, standard voltages and sockets, etc., and supplementary researches on lighting equipment, colour, etc.

There were also numerous resolutions bearing upon lighting education; for example, that the subject of illumination should receive greater consideration in post-primary schools and in all architectural colleges, that in each country there should be at least one full course of illuminating engineering available, and that all public utilities should include on their staffs technically trained representatives able to give advice on lighting matters to the public.

Research in Wood Preservation.

THE problems of wood preservation are of world-wide interest, perhaps never more so than at the present time of economic stress, when the world is threatened with a shortage of its timber supplies. The discussion on this subject, held under the chairmanship of Sir Alexander Rodger, in the Department of Forestry, Section K (Botany), at the meeting of the British Association on Sept. 24, was therefore opportune, and served a valuable purpose in directing attention to research in progress in Great Britain upon a subject of wide economic importance. The proceedings took the form of a series of short papers [1] by members of the staff of the Forest Products Research Laboratory, Princes Risborough. Mr. R. S. Pearson, director of the Laboratory, gave a brief review of the whole field of investigation, in which he stressed the view that co-operation in research between the different groups of workers is essential to the successful progress of this work. Development of new methods in wood preservation is no longer limited to devising ways and means of introducing powerful antiseptics into timber and demonstrating their efficiency by durability and service tests. Viewed at a much wider angle, the work involves biological studies of the organisms causing decay, and investigations into the effect of these organisms upon the chemical constitution of wood. The scope of the work, therefore, calls for the co-operation of mycologist, entomologist, chemist, engineer, and workers in other branches of the study of timber, particularly in relation to its structural and physical properties.

Mr. K. St. G. Cartwright dealt with some of the methods used for the testing in the laboratory of the relative value of different preservatives against wood-destroying fungi. The comparative value of tests on artificial media and on wood blocks was discussed, but it was pointed out that, up to the present time, no standard method of testing wood preservatives has been adopted throughout the world, so that the results obtained by different workers in this field are not strictly comparable. In June 1930 a conference was held on this subject in Berlin, when investigators from different countries reviewed the position and inquired into ways and means of establishing recognised standard international tests for use in determining the value of wood preservatives (Nature, **126**, 921; Dec. 13, 1930). The difficulties of standardising tests are considerable, and these were summarised by Mr. Cartwright. Although laboratory tests may give useful information for comparing the relative value of preservatives and also furnish an idea of the concentrations required for commercial use, it is necessary to supplement these by large-scale field tests. Such tests are in progress on different sites of varying soil and climatic conditions and supplement the investigations carried on in the laboratory.

The problems of wood preservation in relation to damage by insects to structural and manufactured timber in Great Britain were described by Dr. R. C. Fisher. The two groups of insects primarily concerned are the Powder-post beetles (Lyctidæ) and the Furniture beetles (Anobiidæ), to which the Death-watch beetle *Xestobium rufovillosum* belongs. The *Lyctus* beetles cause serious damage to the sapwood of partly and recently seasoned hardwoods, and the most satisfactory methods of preserving wood against damage caused by them consists in periodic inspection of stores of susceptible timbers, elimination of sapwood, and the maintenance of clean and tidy premises in timber yards and factories. The use of preservatives or insecticides has a limited value for the treatment of timber in buildings. The Death-watch beetle presents a much more difficult problem, for, although a number of palliative measures are available against this insect, knowledge of the details of its life-history are lacking. It is believed that the acquisition of a fuller knowledge of the biology and physiology of the Death-watch beetle is the most helpful contribution which can be made towards the solution of this problem, and will not only form a sound basis for the application of improved control measures, but will also shed further light on the mode of nutrition of wood-boring insects, a subject upon which existing knowledge is particularly meagre.

Mr. W. G. Campbell then discussed the problems of wood preservation from the point of view of the wood chemist. Current work on the chemistry of decay of wood by fungi and insects was summarised and the suggestion made that, if decay could be considered in terms of its ultimate chemical effect on wood substance, the future objective of preservative treatment might be the inhibition of certain definite chemical reactions instead of the poisoning of all organisms which might attack timber. Briefly, the lines along which such work is being developed can be considered under two headings: (1) the characterisation of the chemical reactions which take place during decay, and (2) the study of ways and means of treating wood so that the key reactions are inhibited. Existing knowledge of the chemical reactions caused by fungi on timber far exceeds that available on the effect of wood-boring insects, partly due to the lack of information upon the details of their life-history and development.

Whilst investigations into these problems are of paramount importance in the development of new methods of preservation, it is imperative that the best use should be made of preservatives at present available. The value of such substances depends to a large extent upon the degree of penetration achieved in their application. This aspect of the study of wood preservation was described by Mr. J. Bryan, who stressed the necessity of deep impregnation of antiseptics for the preservation of exposed timber and discussed different ways of obtaining this. A brief account was given of the various methods of impregnation by pressure difference and of methods depending on the diffusion of water-soluble preservatives. Special attention was directed to the value of incising as an aid to the satisfactory treatment of refractory timbers, a process now being used commercially in connexion with the impregnation of Douglas fir railway sleepers.

Sir Alexander Rodger referred briefly to the work on wood preservation in progress at the Forest Research Institute, Dehra Dun, and again emphasised the value of co-operative work when each subject concerned has its own contribution to add to the progress of the investigation as a whole. A short general discussion followed, to which members of industries interested in wood preservation contributed.

---

[1] To be published in forthcoming numbers of *Forestry*, the journal of the Society of Foresters of Great Britain.

University and Educational Intelligence.

Edinburgh.—Dr. C. B. Williams, lecturer in agricultural and forest entomology, has requested permission to resign as from March 31, on his appointment as head of the Department of Entomology at Rothamsted Experimental Station.

The degree of D.Sc. has been conferred on R. M. Craig for a thesis on "Geology of the Outer Hebrides—North Harris and Uig, Morsgail and Aline in Lewis".

A Theresa Seessel research fellowship, for the promotion of original research in biological studies, of the value of 1500 dollars is being offered by Yale University. Preference will be given to candidates who have already obtained their doctorate, and have demonstrated by their work fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year, October to June. Applications should be made to the Dean of the Graduate School, New Haven, Connecticut, U.S.A., before March next.

The twentieth annual Conference of Educational Associations has been arranged for Jan. 4–11, at University College, London, under the presidency of Sir William Rothenstein. All members of affiliated associations may attend any of the meetings, except those which are definitely set aside for members only. Non-members also may purchase tickets for all open meetings from the secretary, at five shillings each. The presidential address will be given on Jan. 4. On the same day, Dr. Emmanuel Miller will deliver a lecture on "The Difficult Child: Sociological *versus* Individual Interpretation". Other lectures include Mr. J. Howard Whitehouse on public schools and public life, and Mrs. C. B. S. Hodson on the desirability of including biology in the school syllabus. On Jan. 6, a popular lecture on comets and shooting stars will be given by Sir Richard Gregory. A discussion has also been arranged on the film in education. The chairman of committee of the Conference is Mr. W. W. Vaughan, the honorary treasurer, Miss H. Busk, and the secretary, Miss M. A. Challen, 29 Gordon Square, W.C.1.

Birthdays and Research Centres.

Dec. 27, 1887.—Prof. E. N. da C. Andrade, Quain professor of physics in the University of London.

I am at present engaged on three main lines of research: the accurate determination of the velocity of sound in gases by new methods, which involves a more exact knowledge of the behaviour of a column of vibrating gas in a tube; the laws governing the flow of crystalline solids, both in the poly-crystalline and in the single crystal state, in connexion with which the electrical properties of metal single crystals are under investigation; and the theoretical and experimental aspects of the viscosity of liquids. In respect of flow, the liquid state seems to be in many respects more analogous to the solid than to the gaseous state. In this connexion it is to be noted that there are very few reliable data on the viscosity of elementary substances in the liquid state. Such measurements are badly needed, and I am about to undertake an experimental investigation to remedy this deficiency.

Dec. 28, 1853.—Dr. Alexander Scott, F.R.S., director of scientific research in the British Museum and formerly superintendent of the Davy Faraday Research Laboratory of the Royal Institution.

In the past my work has been mainly on problems relating to atomic weights, on which I have still much unpublished.

Since the War my occupation has been to discover methods for preserving and restoring museum objects of every kind. This presents a never-ending series of scientific problems of the most fascinating nature. Through one's hands are continually passing marvellous specimens in gold, in carnelian and bronze, concerning which one must ask: What has caused this specimen to deteriorate in this way? or, How has the craftsmanship disappeared which thousands of years ago was able to fashion such an article?

The endeavour to find answers to such questions leaves but little time for more purely theoretical investigations.

Dec. 28, 1882.—Sir Arthur Eddington, F.R.S., Plumian professor of astronomy and experimental philosophy in the University of Cambridge.

My main work this year has been in the borderland between relativity theory and quantum theory. For some years, the position was that not much further progress in relativity theory could be expected until the quantum theory advanced to meet it; but now the two theories are in contact, and Dirac's linear wave equation seems to provide a bridge between them. This gives a strong hint as to the direction in which relativity theory should be extended in order to cope with atomic phenomena. Following the hint, I have been working on the relativity side of the bridge, using as additional clues the values of the absolute constants of Nature. Attention was at first confined to the fine-structure constant 137; but lately further insight has been obtained from the cosmical constant and the mass-ratio of the proton and electron. The work is, I hope, progressing towards the direct formulation of a 'geometry' from which these constants will emerge naturally.

Dec. 29, 1873.—Prof. H. Stanley Allen, F.R.S., professor of natural philosophy and director of the Physics Research Laboratory in the United College of the University of St. Andrews.

Since my induction in 1923 to the St. Andrews chair —described on its foundation as a chair of natural and experimental philosophy—my work has been concerned mainly with quantum theory and with spectroscopy. My interest in the historical and philosophical aspects of natural philosophy has increased of late years, and a small volume dealing with recent developments in atomic physics is now passing through the press.

The new laboratory opened by Sir William Bragg in 1925 has provided opportunity for experimental research by zealous helpers on the subject of band spectra, the secondary spectrum of hydrogen in particular. The request from the Editor of Nature for a statement as to the chief investigations now in progress reached me two days after the disastrous fire in the chemical and physical laboratories. Apparatus for physical investigation and for advanced students has been to a large extent destroyed, and for the moment experimental research is at a standstill.

My hopes for the future may be expressed in a sentence familiar throughout Scotland—*nec tamen consumebatur*.

Dec. 29, 1878.—Dr. W. D. Lang, F.R.S., Keeper of the Department of Geology in the British Museum (Natural History).

While the neontologist sees the organic world as a single cross-section, the palæontologist views it as a series of superposed cross-sections, and seeks morphological series collected from consecutive strata, series which, when he has applied certain safeguards, he may have reason to suppose approximate to true lineages. He is thus able, with suitable material, to test the evidence afforded by individual growth-stages and their bearing on recapitulation. Further, in so far as his series represent true filiations, their terms show by what changing characters evolution can be traced. They also call in question the selection-value of characters. Lineages, again, show trends, in following which characters of parallel lineages are seen to run similar courses, and those of one lineage often to run their course regardless of the stage reached by other characters of the same lineage—facts which, again, bear upon the theory of evolution by means of natural selection.

Palæontological investigation, therefore, should, I think, be carried out along the lines of bed-by-bed collecting; of tracing lineages; of noting growth-stages; and of observing trends and the evolutionary history of individual characters; and, whether investigating Palæozoic corals, Cretaceous Polyzoa, or the faunal succession of the Dorset Lias, I have followed, and continue to be guided by, these methods of research.

Dec. 30, 1850.—Dr. William Garnett, formerly educational adviser to the London County Council.

While at Newcastle I was almost wholly occupied with the development of the College of Science into a complete university college. I also gave considerable attention to electrical engineering, and as honorary electrical engineer to the Royal Jubilee Exhibition of 1887, I arranged the first public display of the Parsons turboelectric generators, lighting therewith by means of high-power incandescent lamps a floor area of three acres. At the same Exhibition I exhibited for the first time a colliery engine plane with full-sized tubs electrically driven on a main and tail rope.

After entering the service of the L.C.C. in 1893, my time was so completely occupied in educational administration that it was impossible for me to carry out original work. My main object was to secure that the polytechnics should not be congeries of independent science and art classes, but organised educational institutions with competent principals, and teachers paid by fixed salaries and not on the examination results of their own classes.

Societies and Academies.

London.

Society of Public Analysts, Dec. 2.—H. W. Buston: A micro-method for the determination of uronic anhydride groups in pectic substances. The method involves distillation with dilute hydrochloric acid and measurement of the resulting carbon dioxide. The process is complete in 60-70 min., and the results are as accurate as those given by the macro process.—**N. E. Cocchinaras:** The composition of linseed oil. From the results of bromination experiments it is concluded that the linolenic acid of linseed oil is present in only one isomeric form, namely, that yielding the crystalline hexabromide. Less than two per cent of oleic acid was found, and the solid fatty acids were proved by fractional distillation to consist only of palmitic and stearic acid.—**T. Hedley Barry:** Oil from Malayan *Aleurites Montana* and the properties of Hong Kong oil. Oil from the seeds of *Aleurites Montana* from the Malay States had an abnormal refractive index, which was lower than any recorded for the oil of *A. Fordii*. It also gave abnormal results in the polymerisation test.—**S. G. Clarke and W. N. Bradshaw:** The calcium fluoride method for the determination of fluoride, with special reference to the analysis of nickel-plating solutions. In the presence of an excess of calcium chloride to reduce the solubility of the precipitate, calcium can be quantitatively precipitated as calcium fluoride without simultaneous precipitation of calcium carbonate. Iron does not interfere if it is first reduced to the ferrous condition by means of hydrazine, and the adsorption of calcium sulphate is largely prevented by the presence of ammonium chloride, which increases the solubility of the calcium sulphate.

Dublin.

Royal Irish Academy, Nov. 30.—C. H. Rowe: A characteristic property of systems of paths. Unless a system of curves in a space of N dimensions ($N>2$) consists of the paths of a linear connexion, the subspace generated by the curves that i[illegible]e from a point in the directions of a linear vector-sp[illegible] in general have a singularity at this point, th[illegible] nd partial derivatives of the functions involved i[illegible] parametric representation being discontinuous there.

Paris.

Academy of Sciences, Nov. 16.—Jules Drach: The determination of the linear elements for which there exists a triangular network of geodesics. Generalisations.—**J. Costantin, P. Lebard, and J. Magrou:** The influence of a period in the mountains on the productivity of the potato. Tubers of potato from healthy plants previously cultivated at a height of 1650 metres have given better developed and higher yields than similar tubers of the same origin but from plants cultivated at a low level in the preceding year.—**A. Lumière and A. Seyewetz:** The preparation of fine grain negative images by development. Normally, the size of grain of the negative developed in the usual way is a function of the initial size of the particles of silver bromide forming the sensitive emulsion. Paraphenylenediamine, in presence of caustic alkalis or carbonates, behaves like other developers from this point of view, but under certain conditions (feeble alkalinity) may give images with much finer grain than those of the initial emulsion. A formula of a suitable developer is given, together with reproductions of the same plate (× 500) with two developers showing difference in grain size.—**E. Mathias:** Ascending flashes of lightning.—**Al. Pantazi:** Certain projective properties of families of surfaces.—**P. J. Myrberg:** Systems of functions which admit of a theorem of algebraical addition.—**M. Ghermanesco:** The successive means of an n-metaharmonic function.—**L. Goldstein:** The quantic mechanics of various simple photo-chemical processes.—**G. Déchène:** Peculiarities of lead chloride semi-conducting cells.—**Garrigue:** The electrical conductivity of acetone with a continuous current.—**J. Jaffray:** Some properties of thermocouples in a vacuum. Two types of thermocouples designed for the measurements of weak alternating currents were studied. The relation between the intensity of the heating current (I) and the deviation of the galvanometer receiving the thermocurrent produced (D) was found to be $D=KI^n$, where n was approximately 2.—**R. Freymann:** The infra-red absorption spectra of mixtures of organic liquids; the hypothesis of an electrolytic dissociation for these mixtures.—**C. Haenny:** The magnetic double refraction of paramagnetic salts in aqueous solutions. Utilising the large Bellevue electromagnet, the results of Elias on the magnetic double refraction of solutions of erbium nitrate were confirmed. Solutions of cerous nitrate give very high magnetic double refraction of negative sign.—**R. Toussaint:** The measurement of fluorescence with a photoelectric cell.—**M. Bourguel:** The influence of substitutions on the frequency of the ethylene line.—**A. Perret and R. Perrot:** The hydrolysis of nitrosyl chloride and of nitrogen peroxide by caustic potash. These reactions are shown to depend on the concentration of the solution of caustic potash. Nitrosyl chloride gives not only nitrite and chloride but also nitric oxide, the latter in proportions varying from 9 per cent to 42 per cent of the total nitrogen. Nitrogen peroxide also gives some nitric oxide when absorbed in potash solution.—**Raymond Quelet:** Paramethoxymethyl-benzoic aldehyde.—**L. Palfray, S. Sabetay, and Mlle. Denise Sontag:** The dehydration of phenylglycol by potash.—**A. Demay:** The Hercynian tectonic of the southern Cevennes and of the Rouergue district.—**A. Dauvillier:** The synthesis of the polar aurora.—**J. Imbrecq:** Globular lightning with multiple explosions.—**M. Bridel and Mlle. C. Bourdouil:** The evolution of the glucides in the course of the formation of the seed of two varieties of pea.—**A. Guilliermond:** The frequent existence of specialised vacuoles in the anthocyanine cells.—**Ch. Rousseau:** The presence of zooxanthellæ in Æolidia.—**Emile F. Terroine, A. Giaja, and L. Bayle:** The formation of creatine and purin bodies of urine at the expense proteid materials.—**J. Errera, H. Vogels, and L. Haus** Animal and plant proteids. Electrometric analys —**Octave Bailly and Roger Netter:** The isolation carotene from the suprarenal glands. From 30 k grams of suprarenal capsules (ox) 0·3 grams of p carotene was isolated, or 100 mgm. per kilogram fresh glands. Its identity with plant carotene wa established.—**Ugo Lumbroso:** Inoculation of t monkey with strains of bacteria isolated from Tunisian cases of trachoma.

Geneva.

Society of Physics and Natural History, Oct. 22.—A. Brun: (1) The apparent dispersion of the optical axes in peridote and the measurement of $2V$. The author has measured the angle of the axes and the dispersion, eliminating the causes of error arising from the index of the liquid medium and the radiation employed. The examination of the dispersion curves peculiar to the peridote and to the bromonaphthaline show that the radiation 4870 A. to 4880 A. gives the most exact value of the angle $2V$. The author finds $2V_\rho>2V_v$ and for the line H_β (4861A.), $2V=87° 40'$.—(2) The separation of the *ng* and *np* ultra-violet spectra efracted by a doubly refracting prism. The author eparates the *ng* and *np* spectra of a prism by passing hem through a calcite prism, the edge of which is ormal to that of the prism studied (zircon, beryl, eridote). He has proved that colourless zircon is as ansparent for the ultra-violet as quartz.—A. Jayet d G. Amoudruz: The discovery of Magdalenian eposits near Frangy (Haute Savoie). At Douattes, ar Frangy, the remains recently discovered occur two levels. The lower, of Magdalenian age, has rnished flints and bones of mammals. In the upper vel, probably of neolithic age, pottery appears. This posit appears to connect the Magdalenian deposits f Ain with those of Veyrier.

Diary of Societies.

TUESDAY, December 29.

Royal Institution of Great Britain, at 3.—Sir William Bragg: The Universe of Light (Christmas Lectures) (1): The Nature of Light.

WEDNESDAY, December 30.

British Astronomical Association (at Sion College), at 5.

THURSDAY, December 31.

oyal Institution of Great Britain, at 3.—Sir William Bragg: The Universe of Light (Christmas Lectures) (2): Light and the Eye.

FRIDAY, January 1.

unior Institution of Engineers, at 7.30.

SATURDAY, January 2.

oyal Institution of Great Britain, at 3.—Sir William Bragg: The Universe of Light (Christmas Lectures) (3): Light and Colour (1).

Public Lectures.

MONDAY, January 4.

oyal Geographical Society, at 3.30.—The President: South and East (Christmas Lecture for Young People).

WEDNESDAY, January 6.

University College, at 3.—Sir Richard Gregory, Bt.: Comets and Shooting Stars.

Belfast Museum and Art Gallery, at 8.—Mrs. H. Richardson: Costume and History.

Annual Meeting.

January 4 and 5.

Mathematical Association (at London Day Training College).

Monday, Jan. 4, at 3.30.—Sir Arthur Eddington: The Decline of Determinism (Presidential Address).

At 5.—Prof. S. Brodetsky: Modern Dynamics in Astronomy, Relativity, and Quantum Theory.

uesday, Jan. 5, at 10 A.M.—Discussion on The Report of the Association of University Teachers on Entrance Tests and Initial Degrees.

At 11.15 A.M.—Dr. S. Verblunsky: The Foundations of Mathematics.

At 12.15.—Prof. A. Lodge: Interpolation by Central Differences.

At 2.30.—G. Frecheville: The Application of Mathematical Methods to Research Work in Agricultural Economics.

At 3.30.—Discussion on Calculus and Co-ordinate Geometry at the School Certificate Stage, with special reference to the Additional Mathematics Syllabus of the Joint Matriculation Board of the Northern Universities.

Conferences.

December 29 to January 1.

cience Masters' Association.

esday, Dec. 29 (at King's College for Women), at 8.15.—Dr. C. Norwood: Presidential Address.

Wednesday, Dec. 30 (at Imperial College of Science and Technology), at 10.15 A.M.—Prof. J. Thorpe: The Schools and Research (Lecture).

At 11.45 A.M.—Discussion on The Correlation of Mathematics and Science.

At 5.30.—E. G. Savage: Demonstration of Experiments on Colour.

At 6.15.—F. A. Meier: Lecture-Demonstration.

(At King's College for Women), at 8.15.—Dr. G. C. Simpson: Modern Weather Forecasting (Lecture).

Thursday, Dec. 31 (at Imperial College of Science and Technology), at 10 A.M.—Discussion on The Size of Classes for Practical Work in Science.

At 11.30 A.M.—Lecture-Demonstration by the Television Society.

At 5.30.—F. A. Meier: Lecture-Demonstration.

At 6.15.—E. G. Savage: Demonstration of Experiments on Colour.

(At King's College for Women), at 8.15.—Prof. E. W. MacBride: The Inheritance of Acquired Characters (Lecture).

January 4 to 11.

Conference of Educational Associations (at University College).

Monday, Jan. 4, at 3.—Sir William Rothenstein: Presidential Address.

At 5.—Dr. E. Miller: The Difficult Child: Sociological *v.* Individual Interpretations (Lecture) (British Psychological Society—Education Section).

Tuesday, Jan. 5, at 2.30.—Discussion on The Film as an Instrument of Humane Education (University of London Animal Welfare Society).

At 3.—J. H. Whitehouse: Public Schools and the Public Life (Lecture) (Society for Experiment and Research in Education).

Wednesday, Jan. 6, at 3.—Sir Richard Gregory, Bt.: Comets and Shooting Stars (Lecture) (School Nature Study Union).

At 5.30.—Prof. D. Laurie: Biology in Schools (Lecture) (Association of Assistant Mistresses).

Thursday, Jan. 7, at 2.30.—Mrs. C. B. S. Hodson: Desirability of including Simple Biology and Heredity Teaching in the School Curricula (Lecture) (Eugenics Society).

Friday, Jan. 8, at 2.—Discussion on Physical Education in Schools (Medical Officers of Schools Association).

January 6 to 11.

Geographical Association (at London School of Economics).

Wednesday, Jan. 6, at 9.30 A.M.—Opening of Publishers' Exhibition and Address by Miss E. H. McLean.

At 11 A.M.—Discussion between the Historical Association and the Geographical Association: What is Historical Geography?

At 2.—Sir Leslie Mackenzie: A Health Administrator's Attitude to Geography (Presidential Address).

At 5.30.—S. A. S. Hozayen: The Expansion of the Arabs and their Contribution to Geography (Lecture).

Thursday, Jan. 7, at 11 A.M.—Mrs. H. Ormsby: The Part played by the Limestones in the Human Geography of France (Lecture).

At 12.—J. Fairgrieve: Demonstration Lesson with Films.

At 2.—Demonstration of Amateur Films.

At 3.—J. Fairgrieve: The Use of Films in Teaching.

At 5.—Prof. P. F. Kendall: How Britain became an Island (Lantern Lecture).

Friday, Jan. 8, at 10.30 A.M.—Brigadier H. S. L. Winterbotham: New Developments of the 1″ Map (Lantern Lecture).

At 11.30 A.M.—Prof. Gerhard Schott: The Humboldt Current in Relation to Land and Sea Conditions on the Peruvian Coast (Lantern Lecture).

At 2.45.—Discussion on The Difficulties of using the Lantern in Primary Schools.

Discussion on The Scope and Content of the Geography of the 'rest of the world' in the First School Certificate Examination.

Exhibition.

JANUARY 5 TO 7.

EXHIBITION OF SCIENTIFIC INSTRUMENTS AND APPARATUS (at Imperial College of Science and Technology), 3 to 6 and 7 to 10.

Tuesday, Jan. 5, at 8.—C. C. Paterson: Photocells: The Valves which operate by Light (Lecture).

Wednesday, Jan. 6, at 8.—T. Smith: Photographic Shutters and their Properties (Lecture).

Thursday, Jan. 7, at 8.—Sir Oliver Lodge: Reminiscences (Lecture).
